Ages ranged from 18 to 40 years, with 77 men between 20 and 30. The racial origins reflected approximately the distribution in the general population.

Army aptitude test scores were available for the 58 soldiers in training and 26 combat veterans. Forty-three per cent fell into the highest 5 per cent and only 10 per cent into the lowest 30 per cent.

Only 8 of the 116 did not complete elementary school, and only 3 of these had poor school records. Four of the men attended university and the rest attended high school.

Greatly Diminished Incidence of Significant Psychiatric Data in Successful Soldiers as Compared with Psychiatric Discharges

	Present Series, %	Slater, %	Rosenberg and Lambert, %
Work history			
Poor work record.....	1.0	54.0
Skilled and semiskilled.....	85.0	48.0
Family history.....	14.6	65.7	39.5
Childhood neurotic traits.....	31.0	69.8
Bad home.....	6.8	20.9
Previous personality or mental disorder.....	3.4	40.0	69.0

One hundred and seven men had worked for one or more years; 33 were classified as engaged in skilled work, 58 semiskilled and 16 unskilled. Only 1 had a poor work record.

Thirty-eight had had previous military experience in the militia or cadets.

The family history was considered to be significant where psychoses or epilepsy occurred in the immediate family or first degree relatives, or where neurosis and severe personality maladjustments, such as chronic alcoholism or constitutional psychopathy, occurred in the more immediate family. There were 17 significant family histories. These included 3 cases of epileptic seizures in an uncle, aunt and brother, and schizophrenia in an uncle. If one excludes these as not being a factor in the predisposition to neurosis, there remain 13 positive family histories.

A bad home, in the sense of excessive poverty, drunkenness or family disagreement with constant anxiety and uncertainty, was present in 8 cases, and in half of these one parent deserted the family when the soldier was under 13.

Forty-nine men showed some signs of instability:

- Ten had pulse rates of 90 to 100.
- Fifteen showed nail biting—only 1 severe.
- Twenty-four showed tremor and sweating of the hands—only 1 severe.

Neurotic traits in childhood were present in 36 of the men; 24 had one trait, 7 had two traits and 5 had three traits.

Personality assessment is difficult in one interview, but 18 men could be classed roughly as introverted and 23 as extroverted. Seventy-five fell into neither of these categories. All had made good social adjustments and had normal recreational outlets. None of the men had any spontaneous health or "nerve" complaints.

An effort was made to see if the men understood the principles at stake in this war. I considered them to have good motivation if they could define fascism as an authoritative, dictatorial form of government, if they understood the concept of "master race" as used by the fascists, if they were conscious that fascist and democratic states could not exist side by side and if they felt that there would be no place for them in a world ruled by fascism. A great deal of importance was attached to the last question, and the motivation was graded good, fair or poor. Ninety-four were found to have good motivation, 4 fair and 18 poor.

Four men were downgraded at the time of this study, 1 for base duties in a theater of action and 3 for service in Canada only. These were all in the group of training soldiers. Seven were graded "accept for recheck"; that is, they would be seen by a psychiatrist at the end of a period of training.

COMMENT

The table compares certain of these findings with those of Slater² and Rosenberg¹ in their studies of soldiers with psychiatric disabilities and emphasizes the low incidence of significant psychiatric data in this series. Ebaugh,³ Steinberg⁴ and Schwab⁴ do not give absolute figures, but all report a much greater incidence of signs and symptoms of instability, positive family and developmental histories and poor social and work adjustments as compared with their controls of normal men.

This study was undertaken to evaluate a criticism which few service psychiatrists take seriously; that is, that our standards are too strict and that we screen out men who would make good combat soldiers. If this criticism were valid, one would expect to find more men who do not meet the present screening standards among the unscreened battle veterans than in the screened group of soldiers in training. The soldiers in training went through our screening, and there were indications for the downgrading of 4. All of the "accept for recheck" cases would have had their gradings for full duty confirmed. All the combat veterans enlisted in the Army before adequate psychiatric screening was established, but a natural selection had taken place, with weeding out of the psychiatrically unfit during training, the battle of Britain and a long period of waiting before action. All had been through battle stress, and none had developed a psychiatric disability. That our screening standards are no stricter than natural battle stress screening is shown by the fact that none of these men whose stability was unaffected by battle would have been rejected. Thus our errors are, if anything, in the direction of leniency.

It is interesting that only 15 of the training soldiers had clear family and developmental histories and presented no signs or symptoms of instability, but apart

from the 4 that were downgraded their original assessments were correct, and they were making good soldiers.

Only 24 of the 58 combat veterans were completely "normal," and yet all of them had seen action without developing any psychiatric disability. This bears out the conclusions of Steinberg,⁶ who says that "for every factor investigated there is a definite overlap of adjusted and maladjusted groups. The number and intensity of these factors evidently are cumulative in their effect and on the adjustment of the individual selectee." In this group the 2 cases showing severe fingernail biting, tremor and sweating of the hands, and 3 of the 5 men presenting three childhood neurotic traits were downgraded. Of the remaining 2, 1 would be accepted for recheck.

It must be emphasized, however, that the total picture of the individual man in his environment must be considered and all significant data evaluated in the light of his present civilian adjustment. The frank neurotic, psychopath or prepsychotic personality is not a diagnostic difficulty, yet it is generally agreed that if only these are rejected a considerable number of men will still break down in training or after minimal stress in a theater of action.

It is the feeling of psychiatrists in the Canadian Army that the maintenance of proper screening standards depends on the experience of the screening psychiatrists with men who break down in training or are returned from overseas because of psychiatric disability. Doubtful cases are accepted for recheck, and the screening psychiatrist receives a copy of the report of the examination at the training center. Study of the percentage and types of these cases that require a lowering of category provides a check on the validity and reliability of the psychiatric evaluations of the individual psychiatrists. It has been found that the rejection rates of the psychiatrists at the same induction centers differ very little in spite of varied training and professional backgrounds and in spite of the lack of objective criteria that can be laid down for rejection. It is not felt that psychiatric screening can ever exclude all psychiatric casualties, but, as Kubie⁶ maintains it should greatly reduce the number occurring in training and under minimal battle stress.

SUMMARY AND CONCLUSIONS

1. Fifty-eight successful soldiers in training (screened) and 58 combat veterans (unscreened) with no presenting psychiatric disability were studied.

2. Screening standards in use at present in induction centers of the Canadian Army were applied. Using these standards, 4 training soldiers were downgraded, 1 to limited duty in a theater of action, 3 to service in Canada only. None of the combat veterans were downgraded.

3. There was no significant difference in the findings in the two groups of men.

4. Ninety-four were found to have good motivation and high morale. This factor can be adequately assessed only after studies of unselected groups have been made.

5. Soldiers who have stood the stress of battle without developing a psychiatric disability and the best soldiers in training are distinguished from their neurotic fellows by being stable, well adjusted and intelligent, with fewer and milder significant psychiatric stigmas.

6. Results of this study indicate that psychiatric screening standards at present employed are not too strict.

ABSTRACT OF DISCUSSION

LIEUTENANT COLONEL J. D. GRIFFIN, R. C. A. M. C.: One essential problem facing the psychiatrist in his examination of recruits at the induction center concerns the answer to the question What are men being selected for? We are prone to think that our primary goal is to get the man through training, and so we select men for training. It is obvious that that is not the only goal of selection. The goal of the soldier is to fight, and so we must select for combat too, and that makes it pretty hard; for the man who is a good fighter and a good combat soldier is not necessarily also able to take the long dreary months of training, discipline, regimentation, education in the classroom sense and the separation from home and family and from his old job. There is another problem facing our psychiatrist. I refer to the unpleasant position the service and civilian psychiatrist finds himself in when he discovers that he is between the pressure of the politicians and the people at the top, who feel that the army is somehow not getting enough men, that the men already in are somehow melting away largely through the efforts of the psychiatrists, and on the other hand the pressure that comes from the training officers, the men in charge of the training camps, who say "You're doing a swell job, only do more of it. We don't want these fellows. They don't make good soldiers. Tighten your standards." There are six ways in which we try to keep our sights on the target. The first is that we use only service psychiatrists for screening recruits. All the psychiatrists in the induction centers are in the army. Secondly, we send the psychiatrists into the field frequently so that they may check up personally on the type of men they have let in. That makes it possible for them to reexamine after six to eight weeks of training many of the men whom they were rather doubtful of at the induction center. This is our so-called Accept for Recheck System. Our figures show that over 60 per cent of these men are making the grade as successful soldiers, which is a reasonable margin of error, I think. Thirdly, we have a social service organization in the army belonging to the medical corps, which checks the social and medical background of doubtful cases. We have had in addition an experimental project under way by which we are deliberately taking into the army through our induction centers men who would ordinarily be rejected because of instability. These men, a hundred of them, are at present in training with a modified training program stressing group psychotherapy and special indoctrination and educational procedures.

Thomas Hodgkin.—Thomas Hodgkin (1798-1866), after graduating in medicine at Edinburgh in 1823 and studying intensively in France and Italy, settled in practice in London and was appointed curator of the pathologic museum and demonstrator of pathology at Guy's Hospital, London. This was one of the first chairs of this particular subject to be created. Hodgkin held it for ten years and made many important studies of the pathologic collections. His paper on the diseases of the "absorbent glands and spleen" published in 1832 first described the disease which Wilks in 1865 named Hodgkin's disease. Hodgkin was noted for his philanthropic labors. He was a close friend of Sir Moses Montefiore, the Jewish philanthropist, and while traveling with Sir Moses in the Orient contracted dysentery and died at Joffa, where he is buried.—Clendening, Logan: Source Book of Medical History, New York, Paul B. Hoeber, Inc., 1942.

THE USE OF PENICILLIN IN RHEUMATIC FEVER

LIEUTENANT COMMANDER ROBERT F. WATSON
(MC), U.S.N.R.

SIDNEY ROTHBARD, M.D.

AND

HOMER F. SWIFT, M.D.

NEW YORK

Although the etiology of rheumatic fever is not fully understood, current data indicate that attacks of this disease are generally preceded by infections with group A hemolytic streptococci. The sequence of events is so regular that one is justified in advancing the hypothesis that the streptococcal infection induces rheumatic fever. Whether group A streptococci are the only infectious agents responsible for rheumatic fever or whether they merely activate some other specific micro-organism or virus and possibly act in concert with it to produce the disease has not been determined. The temporal relationship between the hemolytic streptococcal infection and the attack of rheumatic fever is generally not immediate. In fact, the usual sequence of events is streptococcal infection, quiescent period, rheumatic fever. These phases have been designated as I, II and III respectively. It has been shown that if the initiating or inducing streptococcal infection, phase I, is prevented in susceptible subjects, then rheumatic fever fails to occur.¹ This is presumably the basis for the prophylaxis of rheumatic fever by the sulfonamides.

With these relationships in mind, it appeared rational to test the influence on the course of rheumatic fever of such a potent antistreptococcal agent as penicillin, for it must be admitted that the drug therapy to date is far from satisfactory. Salicylates, and such chemically unrelated drugs as aminopyrine and neocinchophen, appear to act in the tissues by altering their response to the "noxious agent" and not directly on the inducing agent, the hemolytic streptococcus. Penicillin, on the other hand, appears to exert its curative action by inhibiting the growth of certain pathogenic micro-organisms. If, then, the continuing symptoms of rheumatic fever are due to the persistence of hemolytic streptococci in the patient's tissues, it might be expected that complete removal of these micro-organisms by means of penicillin would favorably affect the course of this disease.

It is well established that sulfanilamide, which is known to be effective against hemolytic streptococcal infections, exerts no beneficial influence on rheumatic

fever but often aggravates the symptoms when given during the active phase of the disease.² The sulfonamides, however, often do not completely eliminate hemolytic streptococci from patients with pharyngitis, tonsillitis or scarlet fever.³ It therefore seemed desirable to test the effect on rheumatic fever of the more powerful antibacterial agent penicillin. Sufficient amounts of this drug were made available by Dr. Chester S. Keefer to study this problem, and the present report gives the details of this study.

METHODS

Eight young men with typical acute rheumatic fever were each treated for two weeks with penicillin. During this period salicylates and other antirheumatic drugs were usually withheld as long as seemed justifiable. The changes in signs and symptoms were noted and charted daily as indicated in the case histories. In addition, leukocyte counts, erythrocyte sedimentation rates, nose and throat cultures, electrocardiograms and x-rays of the chest were taken at frequent intervals. Samples of blood were also obtained once a week for determination of antistreptolysin and antifibrinolysin titers and at various intervals after injections of penicillin to determine its concentration in the patient's serum.

The method of administering the penicillin was varied. Two patients received the drug intramuscularly at four hour intervals during the night and intravenously at three hour intervals during the day for two weeks. Four patients were treated in a like manner for the first week and then only by the intravenous route at three hour intervals from 9 a. m. through 12 midnight for the second week. The 2 remaining patients were given penicillin by the continuous intravenous drip method for one week and then intravenously at three hour intervals from 9 a. m. through 12 midnight during the second week. Because of the possible danger of precipitating cardiac failure in patients with acute rheumatic fever, we hesitated to employ the continuous drip intravenously for long periods and particularly to use large amounts of isotonic solution of sodium chloride. For the constant intravenous method 37,500 units was dissolved in 500 cc. of distilled water containing 5 per cent glucose or occasionally in isotonic solution of sodium chloride. The rate of delivery was 35 to 40 drops per minute or 500 cc. every four hours. The individual intravenous injections contained 40,000 units each except in 1 case, in which the dose was 25,000. The intramuscular injections invariably contained 25,000 units.

The Westergren method was used to determine the erythrocyte sedimentation rate.⁴ The antistreptolysin determinations were made according to the method of Todd and modified as previously described;⁵ the antifibrinolysin determinations were made according to the methods described by Tillett, Edwards and Garner and

by Boisvert.⁶ Representative colonies of all hemolytic streptococci recovered from these patients were grouped and typed by the precipitin technic⁷ and tested in vitro for susceptibility to penicillin. These tests for susceptibility, as well as the determinations of serum concentrations of penicillin, were done by the dilution method described by Rammelkamp.⁸ A standard strain of group A hemolytic streptococcus was used as a control in each experiment.⁹ The samples of blood were defibrinated and stored in the ice box at 4 C. for twelve to twenty-four hours before the determinations were made. We have found that specimens of blood may be thus stored for as long as two weeks without demonstrable loss in the concentration of penicillin.

REPORT OF CASES

CASE 1.—History (chart 1).—D. H., aged 23, was admitted on Jan. 8, 1944 on the sixth day of an attack of rheumatic fever. Two previous attacks had occurred when he was 11 and 12 years of age respectively. An upper respiratory infection on December 15 was followed in nineteen days by pain and swelling in the left foot, shoulder, wrist and both knees.

On admission the temperature was 102.2 F., the pulse rate 92 and the respiratory rate 24 per minute. Arthritis was present as charted. The heart was enlarged to the left by percussion. Auscultation revealed a systolic murmur at the apex and a diastolic blow at the base. The blood pressure was 128/65.

Laboratory examination on admission revealed red blood cells 3,610,000, hemoglobin 79 per cent, white blood cells 10,950, erythrocyte sedimentation rate 115 mm. per hour, cultures of the nasopharynx yielding no hemolytic streptococci, electrocardiogram essentially normal with a PR interval of 0.17 second, x-ray examination of chest disclosing heart enlarged in the region of the left ventricle.

Course.—Penicillin was started on the day of admission. During the first twenty-four hours the patient was given 25,000 units intramuscularly every four hours. For the next six days he was given 25,000 units intravenously every three hours during the day and 25,000 units intramuscularly at four hour intervals at night. During the second week he received daily six intravenous injections at three hour intervals from 9 a. m. through 12 midnight. A total of 1,975,000 units was given over the two week period. The temperature remained elevated throughout the period of penicillin therapy. The arthritis increased during the first week to involve as many as ten different joints and gradually diminished during the second week. Three days after penicillin treatment was started the erythrocyte sedimentation rate had increased to 128 mm. per hour. On the sixth day after the cessation of penicillin therapy it was 135 mm. per hour and moderate fever persisted. At this time the patient was started on salicylates, with a prompt drop in temperature to normal.

About three and one-half months after the onset of the attack the erythrocyte sedimentation rate became normal, but the signs of aortic and mitral insufficiency persisted. Convalescence thereafter was uninterrupted.

In this case there was no evidence that penicillin treatment altered the course of the disease. The patient appeared ill until placed under full therapeutic doses of salicylates. The persistence of an elevated erythrocyte sedimentation rate for over three months indicates that the course of the rheumatic fever had probably not been curtailed by the penicillin therapy.

CASE 2.—History.—M. K., aged 18, was admitted on Jan. 11, 1944 with his first attack of rheumatic fever. Early in December 1943 he developed a cold, which was followed about two weeks later by pain and stiffness in the hips and in the toes of both feet. These symptoms persisted intermittently and at times were severe but did not confine him to bed. On January 3 he developed pain, tenderness and swelling of the right ankle, and during the next six days both hips, knees, the left ankle and the foot became involved. On January 9 he was transferred to the U. S. Naval Hospital, Brooklyn, where erythema marginatum was noted over the trunk for only one day. During the two days in that hospital the patient received

Chart 1.—Course in case 1.

about 3 Gm. of acetylsalicylic acid, with partial relief of symptoms. On the day of admission to the Rockefeller Hospital, stiffness in the right elbow was noted for the first time.

On admission the temperature was 100.4 F., pulse rate 80 and respiratory rate 20 per minute. The patient appeared acutely ill and had pallor of the skin and mucous membranes but no rash. There were pain and tenderness of the right elbow, the first interphalangeal joint of the left middle finger and both hips and slight tenderness over the left knee, ankle and the toes of the left foot. The right knee and ankle were painful, tender and swollen. The heart was at the upper limits of normal in size on percussion. A soft systolic murmur was heard along the left sternal border and a third sound at the apex early in diastole.

The blood pressure was 112/28.

On admission the laboratory examination revealed red blood cells 3,400,000, hemoglobin 74 per cent, white blood cells 9,400, erythrocyte sedimentation rate 128 mm. per hour, throat culture yielding group A type 24 hemolytic streptococci, electrocardiogram essentially normal with a PR interval of 0.13 second, x-ray examination of chest disclosing heart slightly enlarged in its transverse diameter.

9. The Standard Strain of group A hemolytic streptococcus number 98 was kindly furnished us by Dr. Chester Keefer.

Course.—On January 12, the day after admission, penicillin therapy was started, and during the next fourteen days he received a total of 3,350,000 units by the intravenous and intramuscular routes. For the first four days the temperature gradually increased daily, so that by the fourth day of penicillin treatment it had reached 103.3 F. and the arthritis had progressed to involve practically every joint in the body. During the next six days the fever gradually dropped to 99.3 F. and the arthritis receded, so that by the tenth day of penicillin therapy only slight pain in the right shoulder, elbow and fingers of both hands was present. The erythrocyte sedimentation rate, however, was 95 mm. per hour. During the next four days, while the patient was still receiving penicillin, the fever and moderate arthritis recurred. Following the cessation of penicillin on January 26 he continued to improve; the temperature again gradually fell to normal, the arthritis receded slowly and the erythrocyte sedimentation rate declined to 45 mm. per hour by February 11. During the first week of penicillin therapy he developed a short systolic murmur at the apex, which disappeared again as he improved otherwise. The PR interval increased from 0.13 second on admission to

August 1929. A mild sore-throat on Jan. 7, 1944 was followed in two weeks by pain and stiffness in both ankles. The day prior to entry, substernal pressure was noted.

On admission the temperature was 103.9 F., the pulse rate 116, and respiratory rate 22 per minute. The right shoulder, hip and left knee were painful and tender. Both ankles were painful, tender, swollen, red and hot. The heart was slightly enlarged by percussion, and at the base a rough coarse, leathery sound was heard throughout systole. The blood pressure was 120/80.

The laboratory examination on entry revealed red blood cells 4,150,000, hemoglobin 79 per cent, white blood cells 10,450, erythrocyte sedimentation rate 119 mm. per hour, cultures of nasopharynx yielding many group A type 17 hemolytic streptococci, electrocardiogram essentially normal with a PR interval of 0.20 second and a rate of 120 per minute, x-ray examination of chest disclosing slight enlargement of the heart in its transverse diameter.

Course.—Penicillin, started the day after admission, was given by continuous intravenous drip for the first week and by the interrupted intravenous method during the second week. He received a total of 3,295,000 units during the two weeks of treatment. During the first twenty-four hours after admission the arthritis progressed to involve the right knee and then gradually receded during the next few days, so that by the fifth day of penicillin treatment the patient was asymptomatic with the exception of epistaxes. The erythrocyte sedimentation rate, however, remained high and he developed first degree heart block, which persisted until twelve days after the discontinuance of penicillin. On the ninth day of penicillin therapy mild arthritis recurred involving the knees, elbows and shoulders and persisted until nine days after this drug was stopped. By this time the patient was afebrile and the erythrocyte sedimentation rate had decreased to 65 mm. per hour. His convalescence was uneventful thereafter.

Although it is difficult to evaluate the effect of penicillin in this case, it would appear that this patient had a rather mild attack of rheumatic fever with a single cycle of activity so often seen in persons of this age group.

CASE 4.—History.—H. P., aged 24, was admitted on January 14, 1944 with his first attack of rheumatic fever. On December 18 he developed a sore throat. Two days later pain was first noticed in the left hip and foot and subsequently in both feet and knees. During the next fortnight the joint pains spontaneously subsided, and he felt well for about five days. On January 9 he again developed pain in both feet and two days later his ankles became swollen. On the day before admission both knees became swollen and painful, and slight precordial discomfort was noticed.

On admission the temperature was 103.4 F., pulse rate 106, and respiratory rate 26 per minute. The patient appeared acutely ill. Both elbows were slightly painful. The knees, ankles and metatarsophalangeal joints of both feet were painful, tender, swollen, red and hot. The heart was at the upper limits of normal in size to percussion and there was a low pitched systolic murmur at the apex and a soft systolic blow along the left sternal border.

The blood pressure was 134/75.

The laboratory examination on admission revealed red blood cells 4,670,000, hemoglobin 73 per cent, white blood cells 12,150, erythrocyte sedimentation rate 80 mm. per hour, cultures of the nasopharynx yielding group A type 30 hemolytic streptococci, electrocardiogram showing normal rhythm, rate 116 per minute, PR interval 0.20 second, T₁ upright, T₂ diphasic, T₃ negative and RT₂ segment elevated, x-ray examination of the chest disclosing the heart normal in size and shape.

Course.—On the day after admission penicillin therapy was started. During the first week the patient received 4,000 units intravenously at three hour intervals during the day and 25,000 units intramuscularly at four hour intervals during the night. Following the institution of penicillin treatment, the

Chart 2.—Course in case 3.

0.17 second on January 24 and then again decreased to 0.13 second by February 11. At this time he was started on 9 Gm. of acetylsalicylic acid daily. About the middle of February he developed an intercurrent group A hemolytic streptococcal infection, but other than a slight fever and leukocytosis at this time and a transient rise in his erythrocyte sedimentation rate one week later there was no evidence of an exacerbation in his rheumatic activity.

Although this patient had a definite remission of his signs and symptoms during the early part of the penicillin treatment, he suffered an exacerbation later while still receiving the drug; this suggested that his disease was running a polycyclic course. Moreover, he still had signs of active infection when salicylates were started fifteen days after penicillin was stopped; and following the discontinuance of salicylate three months later, the erythrocyte sedimentation rate again became elevated, indicating persistent rheumatic activity.

CASE 3.—History (chart 2).—J. M., aged 31, was admitted on Feb. 5, 1944 on the sixteenth day of an attack of rheumatic fever. A previous attack of polyarthritis, probably due to rheumatic fever, lasting three to four weeks had occurred in

patient's arthritis involved progressively the right hand, wrist, both elbows, shoulders and the sternoclavicular and acromioclavicular joints. On the sixth day after starting treatment the erythrocyte sedimentation rate had reached 112 mm. per hour. His polyarthritis then rapidly cleared and the temperature fell to a normal level. During the second week the patient received 40,000 units of penicillin every three hours from 9 a. m. through 12 midnight. During this time the temperature did not exceed 100 F., the arthritis was much improved and the erythrocyte sedimentation rate decreased to 30 mm. per hour. Nine days after discontinuance of the penicillin he was afebrile, his white blood cell count was within the limits of normal and the erythrocyte sedimentation rate had decreased to 15 mm. per hour. He continued, however, to have some pain and tenderness in both elbows. Two days later pain recurred in both hips and the right knee and during the next forty-eight hours progressed to involve the spine and the left knee. He again became febrile; the white blood cells and the erythrocyte sedimentation rate increased. At this time 9 Gm. of acetylsalicylic acid was given daily, which induced a prompt disappearance of fever and arthritis except for slight pain and tenderness in the elbows which persisted for several weeks, although the erythrocyte sedimentation rate and white blood cells rapidly fell to normal levels.

As indicated by the history and hospital course, this patient's disease was probably polycyclic in type. Penicillin therapy was apparently started during the second cycle of activity, and the remission which occurred during the latter part of the treatment probably represented the natural course for his disease. The recurrence in activity following the cessation of penicillin treatment indicates that this drug was not effective in curing the rheumatic fever.

CASE 5.—History.—W. W., aged 20 years, admitted on March 1, 1944, had postscarlatinal arthritis when 14 years old and for many years had suffered attacks of paroxysmal tachycardia. About February 1 he developed nasopharyngitis. Three weeks later, and one week prior to his admission, pain in both feet, ankles and elbows occurred. On the day before admission the hips and shoulders became involved, swelling of the left knee appeared and substernal discomfort was noticed.

On admission the temperature was 101.4 F., pulse rate 96 and respiratory rate 28 per minute. The patient appeared moderately ill. The elbows, hips and knees were painful and there were small effusions in both knee joints. The left foot and ankle were tender, painful and hot. Examination of the chest revealed slight dullness, with a moderate number of moist rales below the angle of the right scapula. The heart was slightly enlarged to percussion and there was a soft systolic murmur along the left sternal border. The blood pressure was 105/60.

The laboratory examination on admission revealed red blood cells 3,870,000, hemoglobin 84 per cent, white blood cells 11,250, erythrocyte sedimentation rate 47 mm. per hour, cultures of the nasopharynx yielding group A type 19 hemolytic streptococci, electrocardiogram showing left bundle branch block with a PR interval of 0.12 second, x-ray examination of the chest disclosing peribronchiolar infiltration at the right base, and the heart slightly enlarged in its transverse diameter.

Course.—On March 2, the day after admission, penicillin therapy was started and during the next two weeks he was given 40,000 units intravenously at three hour intervals during the day and 25,000 units intramuscularly at four hour intervals at night. During the two weeks of treatment he received a total of 3,404,000 units of penicillin. On March 3 the polyarthritis had increased and the erythrocyte sedimentation rate was 52 mm. per hour. It was therefore decided to give him enough salicylates to eliminate the fever and to render him asymptomatic and then withdraw this drug while he was receiving continuous penicillin therapy; hence he was given

1.5 Gm. of acetylsalicylic acid every four hours for three days. Within eight hours after this treatment was started the temperature returned to normal, and within twenty-four hours he was asymptomatic. When the salicylates were discontinued, however, no rheumatic manifestations reappeared and he made an uneventful convalescence. Except for minor changes in the form of the complexes, his electrocardiograms remained essentially unchanged. It was felt that this electrocardiographic abnormality was not related to his rheumatic fever but that the patient probably suffered from the syndrome described by Wolff, Parkinson and White.¹⁰

This patient apparently suffered a mild attack of rheumatic fever with a single cycle of activity which was broken by the salicylate therapy; hence it is very difficult to appraise the value of the penicillin treatment.

CASE 6.—History (chart 3).—J. C., aged 20 years, was admitted on Feb. 4, 1944 on the eighth day of a second attack of rheumatic fever. At the age of 9 he had an attack of polyarthritis. About four weeks and again one week prior

Chart 3.—Course in case 6.

to his present illness he suffered upper respiratory infections with slight fever and malaise. During the week before admission he had migratory polyarthritis involving the feet, ankles, knees, hips, spine and shoulders. He was given 18 Gm. of sodium salicylate and 8 Gm. of sulfadiazine during the six days prior to hospital admission.

On admission the temperature was 102 F., pulse rate 92 and respiratory rate 24 per minute. The patient appeared acutely ill. The right elbow and shoulder were painful and there was slight stiffness of the left elbow. There was pain and tenderness over the right acromioclavicular joint and both hips. Both knees were red, tender, swollen and hot, and the right ankle and the metatarsophalangeal joints of both feet were painful and tender. The heart was slightly enlarged to the left, and at the apex a third sound was heard early in diastole but no murmurs were present. Along the left sternal border there was a definite pericardial friction rub. The blood pressure was 120/70.

The laboratory examination on admission revealed red blood cells 3,790,000, hemoglobin 78 per cent, white blood cells 11,050,

10. Wolff, L.; Parkinson, J., and White, P. D.: Bundle Branch Block with Short PR Interval in Healthy Young People Prone to Paroxysmal Tachycardia, *Am. Heart J.* 5: 685-704 (Aug.) 1930.

erythrocyte sedimentation rate 111 mm. per hour, cultures of nasopharynx yielding group A type 19 hemolytic streptococci, electrocardiogram showing first degree heart block with PR interval greater than 0.32 second, x-ray examination of the chest disclosing accentuated lung markings with a small amount of fluid in the left costophrenic angle, the heart being slightly enlarged in its transverse diameter.

Course.—On the day after admission, penicillin therapy was started with five intravenous injections of 40,000 units each every three hours during the day and two intramuscular injections of 25,000 units at four hour intervals at night, making a total of 250,000 units daily for the first week. During the second week he was given six injections of 40,000 units intravenously daily. Over the fourteen day period he received 3,470,000 units of penicillin. Within thirty-two hours after penicillin was started the patient's temperature had reached 104.7 F. and the arthritis had progressively involved practically every joint. Therefore 4.8 Gm. of acetylsalicylic acid was given over a period of nine hours, which induced a drop in the temperature to 99.6 F., with definite symptomatic relief. Within twenty-four hours after the salicylates had been discontinued,

Chart 4.—Course in case 7.

however, the temperature returned to 103.4 F. and all joint manifestations recurred despite continued penicillin therapy. During the next two and one-half days the high fever and severe polyarthritides persisted. On the sixth day of penicillin therapy 4.8 Gm. of acetylsalicylic acid gave only slight relief, and on the next day the dose was increased to 9 Gm. daily with a prompt drop in temperature and relief of symptoms. This dose daily for the next six days kept the temperature below 100 F. and the arthritis in abeyance. A second withdrawal of salicylates on February 18, while the patient was still receiving penicillin, resulted in a recurrence of both fever and polyarthritides within twenty-four hours. By this time he had received a total of 3,470,000 units of penicillin without apparent benefit; hence this drug was discontinued, and the daily dose of 9 Gm. of acetylsalicylic acid was resumed with another prompt drop in the temperature and relief of symptoms. This medication was then continued for approximately nine weeks, about two weeks after all laboratory data had become normal. His subsequent convalescence was unremarkable.

It is clear that each time this patient received salicylates in sufficient dosage he obtained prompt symptomatic relief, but on withdrawal of salicylates while he

was on continuous penicillin therapy all signs and symptoms of rheumatic activity promptly recurred. It therefore appeared that his disease was not altered by the penicillin.

CASE 7.—History (chart 4).—S. P., aged 21, was admitted on Feb. 4, 1944, the thirteenth day of his first attack of rheumatic fever, which had been preceded by upper respiratory infection on Dec. 7, 1943 and Jan. 15, 1944. Although several episodes of epistaxis had occurred on December 26 and 27, pain in the arches of his feet first appeared on January 23, forty-eight days after the first and eight days after the second upper respiratory infection. The pain increased progressively during the next eleven days and involved also the ankles and knees. The patient had received 13 Gm. of sodium salicylate during the four days prior to hospitalization.

When admitted he appeared acutely ill, with a temperature of 103.2 F., pulse rate 100 and respiratory rate of 22 per minute. There were stiffness in the shoulders, elbows and wrists and slight pain and tenderness over the lower dorsal and upper lumbar spine. The right knee and ankle were painful, tender, swollen and hot. There was a small effusion in the right knee. The heart was slightly enlarged to the left and a soft prolonged, low pitched systolic murmur localized to the apex was present. The blood pressure was 120/75.

The laboratory examination on admission revealed red blood cells 3,930,000, white blood cells 10,950, erythrocyte sedimentation rate 87 mm. per hour, cultures of nasopharynx yielding group A type 36 hemolytic streptococci, electrocardiogram being essentially normal with a PR interval of 0.20 second, x-ray examination of the chest disclosing the heart enlarged in the region of the left ventricle.

Course.—On February 5, the day after admission, penicillin therapy was started with approximately 250,000 units daily by the continuous intravenous drip. Because of thrombophlebitis this form of treatment was discontinued after the first week, and during the second week the penicillin was given intravenously every three hours. He received a total of 3,278,750 units during the two week period. Forty-eight hours after penicillin was started the temperature had reached 105 F. and the polyarthritides had increased in severity. Because of the hyperpyrexia he was given 6.4 Gm. of acetylsalicylic acid over a period of nine hours with prompt symptomatic relief and drop in temperature. Following the withdrawal of salicylates the fever recurred, and polyarthritides again increased in severity despite continuous penicillin therapy.

On the sixth hospital day the electrocardiogram showed first degree heart block with a PR interval of 0.22 second, and on the next day the T waves in leads 1 and 2 became inverted. On the tenth day of penicillin treatment the erythrocyte sedimentation rate had increased to 111 mm. per hour, the temperature was 104 F., and severe polyarthritides was present. On the following day the patient developed temporary nodal rhythm with intraventricular heart block. Because it seemed unwise to withhold salicylates longer he was started on 9 Gm. per day, with a prompt drop in the temperature and pronounced symptomatic relief. Salicylates were continued in this dosage for six weeks, when the erythrocyte sedimentation rate reached a normal level. Attempts were then made to reduce the dose of salicylates, but pain and tenderness recurred in both shoulders, and it was necessary to return to the original dose to keep the patient comparatively symptom free for another two months. It thus seems probable that the penicillin failed to alter the course of this patient's disease.

CASE 8.—History (chart 5).—N. L., aged 21, was admitted March 2, 1944, on the fourth day of an attack of rheumatic fever. Nasopharyngitis on February 12 was followed in sixteen days by severe pain in both shoulders and substernal pressure. Arthritis then progressively involved both elbows, hips, knees and ankles.

On admission the temperature was 104 F., pulse rate 120 and respiratory rate 28 per minute. Pain and tenderness were noted in the right sternoclavicular joint, both shoulders, elbows, knees, ankles and the right hip. The heart was enlarged.

the left. At the apex a presystolic thrill was felt and a low pitched murmur was heard late in diastole. A systolic murmur, poorly transmitted to the axilla, was also present. The first sound at the apex was snapping in character, and at the base the pulmonic second sound was accentuated and greater than the aortic second sound. The blood pressure was 120/70.

The laboratory examination at entry revealed red blood cells 3,670,000, hemoglobin 74 per cent, white blood cells 13,650, erythrocyte sedimentation rate 118 mm. per hour, cultures of the nasopharynx yielding no hemolytic streptococci, electrocardiogram showing normal rhythm, rate 115 per minute, PR interval 0.20 second, T₁ upright, T₂ diphasic, T₃ upright; x-ray examination of the chest disclosing the heart enlarged in its transverse diameter with a straight left border and prominent pulmonary conus, the lungs with hilar vascular shadows enlarged, suggesting pulmonary congestion.

Course.—Although the patient gave no previous history of rheumatic fever, the classic signs of mitral stenosis indicated earlier experience with the disease. Because of the severity of the attack and the early signs of cardiac failure, the patient was started on 9 Gm. of acetylsalicylic acid daily on admission. Penicillin therapy was started on the day after admission with intravenous injections of 40,000 units every three hours during the day and intramuscular injections of 25,000 units every four hours at night. The patient received a total of 3,390,000 units of penicillin during the two weeks of treatment. On the first day of penicillin therapy pulmonary edema appeared, hence the patient was digitalized rapidly, given a diet containing 2 Gm. of salt daily with limited fluids, and placed in an oxygen chamber. The signs and symptoms of cardiac failure responded quickly to this regimen. Because of mild salicylism, aminopyrine was substituted for acetylsalicylic acid on the fourth hospital day and was well tolerated in daily doses of 4.5 Gm. Following the institution of salicylate therapy and then aminopyrine, the temperature fell to normal, the pulse rate slowed and the arthritis decreased definitely. During the second week of penicillin therapy, however, the arthritis increased in severity and several new joints became involved. This cycle of polyarthritis persisted during the week following cessation of penicillin, then decreased; but a third arthritic cycle occurred a few weeks later and a suggestive one a month later while the patient was receiving full doses of aminopyrine. The high erythrocyte sedimentation rate began to decrease in about three weeks and reached normal six weeks after discontinuance of penicillin treatment. The patient's condition began to improve at this time and the weight to increase; convalescence was well established, with only slight pain, tenderness, and stiffness remaining in a few joints. Signs of both mitral stenosis and insufficiency remained; but whether they were more evident than before the present attack of rheumatic fever it is impossible to state.

While the necessity for both antirheumatic medication and digitalis in this patient may have obscured the effect of penicillin, the cycles of arthritis both during and after penicillin therapy indicated that this drug had little if any effect on the course of the patient's disease.

ADDITIONAL OBSERVATIONS

Samples of blood were taken of all patients at varying intervals after the injection of penicillin to determine the concentration of the drug in the patient's serum. These samples were obtained at various times during the periods of treatment, so that the one-half hour level may have been determined on one day, the one hour level on another day, and so on. The variation in the rate of excretion of penicillin from day to day in the same individual probably accounts for the fact that in case 7 in the table the one-half hour, one hour and two hour blood levels were the same, and in case 3 the two hour and three hour blood levels were similar. In addition, the strains of group A hemolytic streptococci recovered on culture from the nasopharynx of 6 of the 8 patients

were tested for their susceptibility to penicillin in vitro. The results of these tests and a summary of the serum concentration of penicillin obtained on each patient are presented in the table. From these data it is apparent that all of the hemolytic streptococci recovered were susceptible to penicillin in concentrations much below the concentration maintained in the patient's blood serum during most of the period of treatment.

It may also be significant that the nasopharyngeal cultures of the 6 patients that were positive for group A hemolytic streptococci on admission became negative for these micro-organisms within a very short time after treatment with penicillin was started and remained negative after this drug was stopped. It is realized that this does not necessarily indicate that streptococci in deeper tissues such as the cervical lymph nodes were completely eliminated by the therapy.

Determinations of the antistreptolysin O and antifibrinolysin titers were made on the serum and plasma

Chart 5.—Course in case 8.

respectively of all patients at weekly intervals during the course of study. The titration curves for both determinations followed courses similar to those that might have been expected among any 8 untreated rheumatic fever patients. The antistreptolysin O titers initially ranged between 100 and 1,200 units and in most instances increased moderately during the first one to two weeks of penicillin therapy and then remained stationary or began to fall slowly; but they usually persisted in an abnormal zone for several months. The antifibrinolysin titers of all the patients were 3 to 4 plus at the time of admission and usually remained elevated for several months.

In none of the 8 patients treated were any definite toxic manifestations to penicillin observed. Both patients 3 and 7, who received the drug by the constant intravenous drip method, developed mild thrombophlebitis. We do not believe, however, that this was necessarily due to the penicillin; it may have been due in part to the glucose solution, as previously pointed

out by Herrell.¹¹ Thrombophlebitis was not observed in any of the patients receiving more concentrated solutions of penicillin in isotonic solution of sodium chloride by vein at three hour intervals.

COMMENT

Eight young men with rheumatic fever have been treated for a two week period during the acute phase of their disease with penicillin. The total dose of penicillin varied from 1,975,000 to 3,470,000 Oxford units, and 7 of the 8 patients received over 3,000,000 units. The routes of administration were varied. Six of the 8 patients received the drug by the intramuscular and intravenous routes intermittently. The remaining 2 were given penicillin by constant drip for one week and then by the intermittent intravenous method for the second week.

All the patients were acutely ill with elevated temperatures and acute polyarthritis and, in addition, 2 of them had pericarditis and 1 developed pulmonary edema the day after admission. There was no evidence that

maintain in the patient's blood a drug concentration greater than that required to inhibit the growth of the patient's own strain of streptococcus.

On admission to the hospital group A hemolytic streptococci were isolated on culture from the nasopharynx of 6 of the 8 patients. It was shown that 0.015 Oxford unit completely inhibited the growth of all 6 of these strains when this amount of penicillin was added to a culture containing from 1,000 to 5,000 bacterial cells. It was also shown that the concentrations of penicillin maintained in the patients' blood during most of the period of treatment were many times that required to inhibit the growth of the streptococci isolated from these patients. Another indication that the dose of penicillin was adequate is that the group A hemolytic streptococci were eliminated permanently from the nasopharyngeal mucous membrane of these patients within a short time after beginning treatment.

Whether or not penicillin would be effective in preventing rheumatic fever if given during phase I or II

* The inoculum for each test contained between 1,000 and 5,000 bacterial cells.

† Intravenous injections contained 40,000 Oxford units except in case 1, in which the dose was 25,000. Intramuscular injections contained 25,000 units.

‡ The constant intravenous drip solution contained 7.5 units per cubic centimeter and was regulated so that each patient received approximately 3,000 cubic centimeters in a twenty-four hour period.

penicillin altered the course of the disease in 7 of the 8 patients. It was difficult to evaluate the effect of this drug in the remaining subject (patient 5). On the second day of penicillin treatment he was started on 9 Gm. of salicylates daily with the object of rendering him afebrile and asymptomatic and then of withdrawing this drug while he was receiving continuous penicillin therapy. This patient made a prompt symptomatic response to salicylates but on withdrawal of this drug the signs and symptoms of rheumatic activity failed to recur; his erythrocyte sedimentation rate dropped to normal and he made an uneventful recovery.

It is now generally conceded that infection with group A hemolytic streptococci usually precedes and probably initiates the attack of rheumatic fever. It moreover appears possible that the hemolytic streptococcus is the only infectious agent involved in the etiology of the disease and that persistence of these micro-organisms in the patient's tissues may be responsible for the continued signs and symptoms of rheumatic activity. It was therefore desirable to know whether the dose of penicillin used was adequate to

cannot be answered as yet; but we do know that the sulfonamides are ineffective in this respect even when given at the onset of phase I. Until the foregoing question can be answered it seems that the chief value of the antibacterial drugs today with respect to rheumatic fever is in the prevention of the streptococcal infection which appears to induce the disease. It would thus seem that, once the preliminary streptococcal infection has started the mechanism leading to the onset of the rheumatic process in susceptible persons, the antibacterial agents now available do not materially alter the evolution of that mechanism. It must be admitted that we have no conclusive evidence that deep seated foci of streptococci may not exist in these patients in spite of their receiving large enough doses of penicillin to remove them from the accessible mucous membranes; for persistence of these micro-organisms could theoretically be responsible for the continued rheumatic activity.

CONCLUSION

Penicillin in doses ranging from 1,975,000 to 3,470,000 Oxford units given over a two week period to 8 young adults with acute rheumatic fever apparently failed to alter the course of their disease.

THE TREATMENT OF ACUTE RHEUMATIC
FEVER WITH PENICILLIN

MAJOR FRANK P. FOSTER

MAJOR GEORGE C. McEACHERN

CAPTAIN JOHN H. MILLER

LIEUTENANT COLONEL FRED E. BALL

LIEUTENANT COLONEL CHARLES S. HIGLEY

AND

MAJOR HARRY A. WARREN

MEDICAL CORPS, ARMY OF THE UNITED STATES

The probable relationship of Lancefield group A hemolytic streptococcic disease to rheumatic fever has led to the therapeutic trial of various antistreptococcic substances in this disease. Swift¹ and Jones² have described the effects of sulfanilamide in acute rheumatic fever. Swift³ and his co-workers⁴ have also reported the results of streptococcic antiserums in this disease. Both of these entirely unrelated substances were found to be of no therapeutic value, and the evidence is suggestive that at times they may have been harmful. In view of these observations, when penicillin became available there was little cause for optimism that it would be beneficial in this disease.

However, because of the great need for a more satisfactory therapeutic agent for rheumatic fever and the knowledge that the value of penicillin in this disease would eventually need to be determined, it was felt that an organized study by producing an answer quickly and economically would, irrespective of the outcome, ultimately prove worth while.

ORGANIZATION OF THE STUDY

Three army air force installations having high incidence rates for acute rheumatic fever and representing three geographic areas were selected. At each of the three posts the same plan of study was followed. Patients selected for penicillin therapy were those who had characteristic joint disease and who presented sufficient additional evidence of rheumatic fever to make them entirely acceptable from a diagnostic standpoint. Patients were not included who had previously received salicylates or sulfonamides. Some were treated as soon as the diagnosis was made, and the remainder after a period of observation of two or three days. Routine blood studies and urinalyses were done. Erythrocyte sedimentation rates were obtained every other day and electrocardiograms every second or third day. A careful record was kept of changes in objective and subjective evidences of the disease. Throat cultures were made at frequent intervals in the majority of the cases.

PENICILLIN DOSAGE USED

Penicillin was administered intramuscularly in doses of 25,000 units at three hour intervals for daily dosage of 200,000 units. In the majority of instances this dosage was continued for five days or until a total of 1 million units had been administered. The dosage was thus twice that ordinarily acceptable for the usual forms of beta hemolytic streptococcic infections.

INTERPRETATION OF RESULTS

Thirty-eight cases were studied. In 3 cases, because of the progression of the disease, the welfare of the patient made it necessary to stop penicillin and substitute salicylates before the completion of the five day period. The clinical impressions of the three groups of observers regarding the results of penicillin therapy are indicated in the accompanying table. A review of the recorded data reveals no consistent pattern which could be attributed to penicillin therapy. In the group of patients in whom the severity of the disease increased during penicillin therapy it was the opinion of the majority of investigators that penicillin was a contributory factor in this change. The possibility that this represents the natural course of the untreated dis-

Chart 1—Acute rheumatic fever penicillin therapy given during a period of gradual improvement of the disease. Cessation of the drug produced no apparent change in the clinical course.

ease in these individuals cannot be excluded. The single case in which improvement appeared following penicillin treatment may similarly represent a spontaneous recovery not infrequently observed in the monocyclic form of the disease.

Clinical Evaluation of the Results of Penicillin Therapy
in Acute Rheumatic Fever

AAF Hospital	No Change	Increased Severity	Improved
A	5	5	0
B	3	4	1
C	11	9	0
	19	15	1

There were no changes in the electrocardiograms which could not be explained by the course of the disease. In 7 instances the erythrocyte sedimentation rate showed a temporary depression during the period of penicillin therapy. This has been observed also in other patients receiving conventional treatment. Two representative cases are illustrated in the accompanying graphs.

BACTERIOLOGIC STUDIES

In 21 cases throat cultures were taken on admission and one or more times during penicillin therapy. The initial culture in 19 was found to be positive for group A

hemolytic streptococci. In all instances the throat cultures became negative for this micro-organism during penicillin therapy. Seven patients were subsequently followed by serial throat cultures. In 1, the throat culture again became positive before penicillin therapy was terminated, in 1 case two days after termination and in the remaining 5 four weeks after termination. The hemolytic streptococci recovered at this time in the latter group of 5 patients were found to belong to different types than were found at the initial examination.

COMPLICATIONS

Urticaria appeared in 4 cases, lasting an average of three and three fourths days and appearing an average of fourteen days after penicillin therapy was started. Three of these episodes of urticaria were followed by increased joint pains and elevation of the pulse rate and temperature.

INITIAL ONSET OF ACUTE RHEUMATIC FEVER DURING PENICILLIN THERAPY

In addition to the cases described in which the therapeutic effect of penicillin in rheumatic fever was studied, 2 patients were observed who developed characteristic manifestations of acute rheumatic fever during the course of penicillin therapy for severe group A

Chart 2.—Acute rheumatic fever progression of clinical disease during period of penicillin therapy, with prompt remission following a substitution of sodium salicylate.

hemolytic streptococcal infections. In these cases the joint manifestations developed two and four days respectively after the initiation of penicillin therapy and thus contrast to the allergic joint manifestations described. It therefore appears evident that penicillin exerts no beneficial influence in rheumatic fever when given after the establishment of the hemolytic streptococcal infection that apparently induces that disease.

CONCLUSIONS

1. A study of the value of penicillin therapy in 38 cases of acute rheumatic fever disclosed no evidence of benefit.
2. In some cases it appeared clinically that the course of the disease was aggravated.

Special Diabetic Food.—Special foods for the diabetic patient are seldom necessary. On the contrary, the effort today is to permit the patient as far as possible to eat the ordinary foods which come to the table, which, with the more liberal carbohydrate diets now in use and with the aid of insulin, is not difficult. There are the further objections that, while specially prepared diabetic foods are sometimes attractive, they are often unpalatable and they vary greatly in percentage composition. The claims made for them are sometimes misleading, and as a rule they are expensive.—McLester, James S.; *Nutrition and Diet in Health and Disease*, Philadelphia, W. B. Saunders Company, 1943.

PENTOTHAL SODIUM INTRAVENOUS ANESTHESIA IN PEACE AND WAR

THE FIRST TEN YEARS OF PENTOTHAL SODIUM INTRAVENOUS ANESTHESIA, JUNE 1934 TO JUNE 1944

R. CHARLES ADAMS, M.D.

ROCHESTER, MINN.

It usually takes several years to establish a new method in any field of medicine. This has been especially true of the introduction of new anesthetic agents and methods of intravenous anesthesia in particular. The attitudes of different members of the medical profession to the introduction of new methods of anesthesia have often been diametrically opposite; the skepticism of some has been overbalanced by the unbounded enthusiasm of others. These widely divergent attitudes have not always worked to the best interest of the new method or agent. The history of the evolution of intravenous anesthetic agents amply bears this out.¹

In the case of intravenous anesthesia the skepticism on the part of many surgeons and anesthesiologists was not entirely without justification. For fifty years anesthetic agents had been introduced for intravenous administration, and only a few of them had produced uniformly safe and desirable anesthesia. Therefore, when pentothal sodium was introduced as another intravenous anesthetic agent it is understandable that many surgeons and anesthesiologists looked askance at the possibilities of its being of unusual clinical significance.

Pentothal sodium was introduced to clinical practice by Lundy in June 1934, so that this month marks the end of the first decade of its clinical use. While some of the ideas with regard to the use of the agent and method have changed, the original conception of its usefulness has been justified many times over, a fact which has been most gratifying to those of us who have had the opportunity to take a part in its development. Intravenous pentothal sodium anesthesia now stands on its own merits as an established method and has passed well beyond the experimental stages of its development.

However, each one of these ten years has brought about changes in our attitude toward the use of the method, its scope, administration and so forth. There are still many things that one should like to know about the pharmacologic action of pentothal sodium. The most important of these are its site of detoxication and the factors which influence its rapidity of detoxication in various persons. We are not at all sure that it is detoxicated by the liver, like its oxygen analogue pentobarbital sodium.

We are now convinced that pentothal sodium does not appreciably interfere with the function of the normal or damaged liver or kidneys and that it does not untowardly affect the metabolic processes of the body in general, provided it is administered with due regard to the patient's physical state.

In spite of the present day pharmacologic and clinical conceptions that have been generally accepted for pento-

From the Section on Anesthesiology, Mayo Clinic.
Read before the Section on Anesthesiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.
1. Adams, R. C.: *Intravenous Anesthesia: Evolution of the Method, Application in Clinical and Military Practice, and Consideration of the Use of the Barbiturates and Analeptics*, New York, Paul B. Hoeber, Inc., 1944.

thal sodium intravenous anesthesia, the opinions of those who have employed the method extensively are still widely divergent, particularly in relation to the types of surgical cases for which it is suitable. Some feel that it is applicable for almost any type of surgical operation. Others are of the opinion that certain limitations must be recognized unless it is used as an adjunct to some other method of anesthesia—particularly for major surgical cases.

Despite the diversity of opinion on the subject, it is possible to make a few general statements regarding the changes that have been made during the past ten years of its use in civilian surgical practice.

When the use of pentothal sodium was introduced, it was felt that its field should be limited to short and minor operations, requiring little or no muscular relaxation, the duration of which would be approximately fifteen to twenty minutes. Used in this manner as the sole anesthetic agent, its field of usefulness was comparatively narrow. Maximal doses were set between 0.5 and 1 Gm.

As physicians became more familiar with the action of pentothal sodium on patients with varying physical states and for different types of operations, many features of its application were clarified. It was found that the solution of pentothal sodium might be used with safety after it had been made up for periods as long as forty-eight hours. My associates and I have reduced the concentration of the solution from the original 10 per cent to 5 per cent and then to 2.5 per cent. This, we feel, has increased the margin of safety of the method and has reduced the incidence of intravenous or extravascular irritation from the solution to practically nil. Furthermore, it became apparent that comparatively long operations which did not necessitate much muscular relaxation could be performed safely and that many patients would tolerate total doses exceeding 1 Gm. if administered over longer periods.

At the same time, it was recognized that debilitated and toxic patients had a lowered tolerance to pentothal sodium and took comparatively small doses to produce surgical anesthesia and that the administration to such patients must be carried out slowly and cautiously. The postoperative sleeping time was found to be more or less in direct proportion to the total amount of the drug administered, the amount of preliminary medicaments used and the capacity of the patient to detoxicate the drug. Additional observations revealed the fact that it was not a satisfactory method of anesthesia for most abdominal operations or for operations in regions where the reflexes were particularly hyperactive, such as those of the nose, throat, larynx and the anal region. Some anesthetists are of the opinion that pentothal sodium anesthesia is satisfactory for such operations and provides sufficient relaxation. We continue to feel that its use for major abdominal operations, unsupplemented, does not carry the margin of safety that may be attained by the use of some methods of inhalation or spinal anesthesia. In other words, the advantages that one hopes to derive are often outweighed by the disadvantages, if the operation is long and complicated and requires profound relaxation.

As a result of these findings the value of intravenous anesthesia in combination with other methods began to become apparent. The principle of such combinations was to take advantage of the desirable features

of pentothal sodium anesthesia without depressing respiration unduly and producing a prolonged post-operative sleep.

One of the important advances was the administration of oxygen during intravenous anesthesia. This served to decrease respiratory depression and to prevent anoxemia and seemed to favor better muscular relaxation and anesthesia using smaller doses of the drug than otherwise would be necessary. The oxygen may be administered by the ordinary face mask, B. L. B. mask, nasal catheter, nasopharyngeal tube or intratracheal tube.

The next step forward was the administration of 50 per cent nitrous oxide with the oxygen or if necessary as high as 70 per cent nitrous oxide. This serves to reduce further the amount of pentothal sodium required and increases the degree of anesthesia and relaxation. This combination of intravenous anesthesia with inhalation anesthesia has broadened the field of intravenous anesthesia and has increased its safety. The administration of oxygen or of nitrous oxide and oxygen is now routine at the Mayo Clinic during pentothal sodium anesthesia.

Combinations of other methods with intravenous anesthesia have been increasing during the last two or three years. This has been chiefly evidenced in its use with local or regional anesthesia. Among the purposes for which intravenous anesthesia may be combined with local or regional anesthesia are the following: (1) to render local infiltration and block anesthesia painless, such as during a block for bunionectomy; (2) during the course of an operation under local anesthesia if the patient is nervous; (3) to supplement local anesthesia that is wearing off or that is not quite adequate; (4) combined with block of the abdominal wall or intercostal block for abdominal operations in certain cases. These combinations result in adequate abdominal relaxation without one's having to employ large and depressing doses of pentothal sodium.

Similarly, intravenous anesthesia has been useful with spinal anesthesia for nervous patients who prefer to be asleep. Comparatively small doses will control nausea and prevent straining during the course of spinal anesthesia or to supplement spinal anesthesia that is wearing off.

Other combinations may be mentioned, such as the use of intravenous anesthesia as an induction to an inhalation or an ether anesthetic and its combination with topical anesthesia for certain operations about the throat, larynx and upper part of the respiratory tract. For certain operations about the head and neck its combination with nitrous oxide and oxygen administered intratracheally has been particularly useful. With an intratracheal tube inserted, a free airway is established and since none of the agents in this combination are flammable or explosive, a cautery may be used freely and without hazard.

As a result of all these things, the frequency of intravenous anesthesia has been gradually increasing in civilian surgical practice over these first ten years of its use. Owing to the combinations mentioned heretofore, pentothal sodium may now be used safely for many operations in which formerly we would have considered it contraindicated.

We continue to recognize certain contraindications. We do not consider intravenous anesthesia to be as

safe for young children as it is for adults. It should not be used for patients who have degenerative diseases of the myocardium, particularly if dyspnea is present. It is not as safe for operations in which the integrity of the airway cannot be assured as for other operations. One should always remember that intravenous anesthesia is another form of general anesthesia and that many of the complications that are associated with the latter can occur under intravenous anesthesia. We still feel that the method is safest when employed in institutional practice, although its use in the office or home is permissible provided the anesthetist has available equipment for establishing the airway and administering oxygen.

Having observed the progress that intravenous anesthesia has made in civilian practice over this ten year period, we have been extremely interested in what its value would be in army and navy medical practice in time of war. At the beginning of World War II we could only assume that it would play an important role for anesthesia in the armed forces. The simplicity of the equipment, the ease of transportation and its fire proof qualities were obviously in its favor, but we could not be sure how adequate it would be for robust soldiers and sailors or for patients in shock.

Doubts as to the safety of intravenous anesthesia for patients in shock were engendered in the minds of many at the very beginning of the war, when reports began to leak through from Pearl Harbor that its use had proved dangerous and even fatal in a number of such cases. At the same time, experience in civilian practice had convinced us that it could be used safely for many types of operations in such cases provided certain precautions were observed. Subsequent experience on the various battle fronts has corroborated the truth of this statement, the details of which may be summarized as follows:

1. A patient in shock, with or without loss of blood, is much more intolerant to pentothal sodium and requires much smaller doses to produce anesthesia than does the same man without shock. As a result, the effective dose of the drug is materially reduced—sometimes to as little as a fourth or a sixth of the usual dose. If this decreased tolerance as a result of shock is taken into consideration throughout the administration, satisfactory anesthesia may be obtained without producing severe respiratory depression or otherwise endangering the life of the patient.

2. Shock should be controlled, at least partially, before the anesthesia is begun. This maxim applies equally to other methods of anesthesia.

3. Previous administration of morphine should be known as to time of administration and size of dose, in order that a cumulative effect of two depressant drugs may not be superimposed.

4. Airways and oxygen equipment are as essential adjuncts to intravenous anesthesia as they are to inhalation anesthesia. Whenever possible, they should be available when the method is used.

The use of intravenous anesthesia for military surgery not only varies from its present use in civilian practice but also varies in the different types of surgical units within the services. In army or navy base or general hospitals its use parallels that in a civilian hospital. When it must be used in setups close to the combat area such as dressing stations, casualty clearing stations and

on the beaches, some of the standard criteria for, and contraindications to, its use must necessarily be subordinated to the urgency of the need for prompt treatment. Perhaps equipment is not readily available or the wounded man may have food in his stomach. In other words, through necessity, certain chances may have to be taken when the method is used under such circumstances.

However, the important consideration here is that the anesthetist has been sufficiently trained in the use of the method and effects of the drug so that he may judge how far he may safely go. The army and navy training programs in various departments of anesthesia throughout the country have been an important factor toward improving anesthesia in the armed forces. We have had letters from all over the world from physicians whom we have trained in our institution and from these reports I should like to draw some conclusions regarding the present status of intravenous anesthesia in military surgery at home and abroad.²

Before the United States entered the war we had obtained some information regarding the use of intravenous anesthesia in the surgical services of the British army and navy and for victims of bombing during the battle of Britain. From these reports it was learned that the method had been useful for preliminary débridement of bomb-burn victims and persons who had sustained minor war injuries. When shock was minimal, intravenous anesthesia did not appear to aggravate the shock further and some went so far as to say that its use appeared to protect somewhat against the increase of this state. Early reports from England bore out experimental work showing that pentothal sodium is not contraindicated when patients are undergoing treatment with the sulfonamide compounds. This is contrary to the former supposition.

Reports of the use of pentothal sodium from anesthetists in the armed forces throughout the world vary somewhat according to the type of hospital in which it is used. Most of the reports, however, tell the same general story: that pentothal sodium is of outstanding value. Statements such as "It's been a godsend," "We couldn't do without it" and "If I had to choose a single anesthetic agent, it would be pentothal sodium" are read from the letters of medical officers abroad every day. One officer who had spent eighteen months in the New Hebrides stated that "pentothal sodium has been a life-saver, used as the sole anesthetic in some cases or in combination with other anesthetics." Most of these reports come from physicians who are trained in anesthesia and who recognize its disadvantages and dangers as well as its advantages. These men recognize the fact that there are many types of injuries and operations in which the method may be hazardous and do not use it under such circumstances. While some comparatively recent reports have come through to the effect that the mortality rate under pentothal sodium anesthesia is higher than it should be, the men who are administering it on the battlefronts say that in most instances the fault lies in improper methods of administration and dosage and improper selection of cases.

I should like to sum up some of this information from the personal experiences of anesthetists in the

² Information quoted from the communications of army and navy medical officers is understood to represent the personal opinion of these officers and does not necessarily reflect the attitude of the army and navy medical services in general.

armed forces at home and abroad. A 2.5 per cent solution is generally employed, but where syringes are scarce 5 per cent solutions or 3.3 per cent solutions are sometimes used. When made up in quantity and kept from exposure to light and air, solutions up to seven and even to ten days old have been employed.

The percentage of cases in which pentothal sodium is used as the sole anesthetic agent or in combination varies. The average appears to be between 25 and 50 per cent. One officer in charge of anesthesia in an outfit immediately behind the front lines stated that, of 500 patients, 95 per cent received pentothal sodium anesthesia. Another, under similar conditions, said that in 78 per cent of operations, excepting those that were intra-abdominal, intravenous anesthesia was used. The distribution of 1,730 anesthetics administered in a base hospital in England over a six months period is shown in the accompanying table.

While the dangers of administering pentothal sodium to a shocked patient who has received a large dose of morphine must be kept in mind, intravenous anesthesia produces better results in robust soldiers or sailors if full doses of barbiturates, morphine and atropine are administered as preliminary medicaments, provided no shock exists. Satisfactory results have been reported by one officer for certain intra-abdominal operations when other methods were not available. In

these cases thorough premedication and slow induction with pentothal sodium were used.

Total doses vary widely, but a possible average may be estimated to be between 1,000 and 2,000 mg. In 1 case 5.9 Gm. was used over a period of eight hours. This demonstrates a fact often repeated, that the total dose of pentothal sodium and its administration over several hours need not be a reason to discontinue its use if the patient's condition remains satisfactory throughout. Some very prolonged and extensive operative procedures are possible, provided a good airway can be maintained and if profound muscular relaxation is not essential. This is evidenced by the following report of a case of multiple fractures resulting from an airplane crash:

While the patient was under pentothal sodium anesthesia the following procedures were performed: open reduction of a compound fracture of the right humerus; suture of the ulnar nerve in the region of this fracture; open reduction of a compound fracture of the right olecranon and application of a cast; reduction of a fracture of the left radius and ulna with cast; reduction of fracture of right tibia and cast. These were done sixteen hours after the injury, shock was treated prior to the operation and 1,000 cc. of blood was administered during the operation.

The types of operations in which intravenous anesthesia has found most favor are too numerous to set down in detail. Most reports state that it is used in almost 100 per cent of orthopedic operations. It is used extensively for the débridement of burns, for skin

grafting, in most operations on the skin, in operations on the eyes and for most operations that do not involve the cranial, thoracic or abdominal cavity or the upper part of the respiratory passages.

Army and navy anesthetists seem to be fully aware of the advantages to be gained by intravenous anesthesia in combination with other methods. As in civilian practice, reports of its use with oxygen, with 50 per cent oxygen and 50 per cent nitrous oxide, and with local, block and spinal anesthesia are becoming routine. In those cases in which it is used for intra-abdominal operations it is supplemented by intracostal or abdominal wall block in most instances. It appears to be becoming more frequently used as an induction to general anesthesia, since it decreases the stage of excitation in some of these patients and also lessens the formation of mucus and secretion.

The fireproof qualities of pentothal sodium and its nonflammable supplementary agents are reported to be of decided advantage in the forward areas, on battle-ships, during bombings or when operations must be performed with emergency lighting equipment which might ignite a flammable anesthetic agent.

While administration of pentothal sodium is by trained medical personnel or under their supervision, it has often been found necessary to utilize the services of nurses or corpsmen, one medical officer supervising the administration of several intravenous anesthetics. Medical officers inform us that many of these corpsmen and nurses have been doing an excellent job, under the proper supervision, and have fulfilled a very useful purpose. The principles of safe administration of pentothal sodium are quickly learned by intelligent nonmedical personnel. The instruction in venipuncture, in this connection, has been of benefit to those who help the medical staff with the administration of plasma and intravenous fluids.

SUMMARY AND CONCLUSIONS

Pentothal sodium intravenous anesthesia has traversed the first ten years since its introduction. During each of these ten years its use has increased generally throughout the country. Knowing that it is an agent of unusual anesthetic value, many of us have purposely overemphasized certain precautionary measures relative to its method of administration, dosage and selection of cases for its use. This attitude, we believe, is justified in teaching the use of a new anesthetic agent, the administration of which is so simple, the effects of which are so rapid and the results so satisfactory in most cases. The trouble has been that in the past many of the potential dangers incident to its use for certain patients and for certain operations have been overlooked or have been outweighed by its desirable effects. It is under these circumstances that untoward effects have occurred which at times have resulted in justifiable criticism of its safety. Pentothal sodium intravenous anesthesia carries as wide a margin of safety as any established method of anesthesia if it is correctly administered and correctly applied. Those who have had a wide experience with the method have naturally found it a suitable method in more complicated surgical interventions than are generally considered to be within its scope. The most important advance has been the recognition of its potentialities when combined with other methods of anesthesia. These

combinations have increased both the scope and the safety of the method.

The value of the method in military surgery up to the present phase of World War II is more than gratifying. In the final analysis, the application of the method in military surgery does not differ materially from its use in civilian practice. The same principles apply to the two, with the exception that the anesthetist must take into consideration those additional factors inherent in war surgery—shock, loss of blood and often the lack of skilled help and equipment. The anesthetist must weigh these additional factors if he would apply the method to the best advantage. The use of intravenous anesthesia up to the present stage of World War II has even yet been too limited to permit one to draw definite conclusions. Its use in military surgery should provide much additional information for those who will use it in future years.

There is still much to learn about intravenous anesthesia, and no doubt our present attitudes will continue to be modified from time to time. Perhaps new and structurally different agents will be evolved which will completely alter our present opinions of the method. Until such changes do occur, one has in pentothal sodium an intravenous anesthetic agent of undisputed usefulness, which has probably resulted in the most significant advance in anesthesiology throughout the last decade.

ABSTRACT OF DISCUSSION

DR. ALICE McNEAL, Chicago: In the earlier work in Germany anesthetists determined the dose by the patient's weight. Dr. Lundy has changed it from a haphazard method to something that is as controllable as inhalation anesthesia. We are grateful to Dr. Adams for bringing up the subject of untoward effects. I have seen statements that there are no warnings and therefore no possibility to anticipate difficulties. I have had Dr. Adams's experience with the prolonged use of the anesthetic producing a depressing effect after the patient has been returned to the room. We have been using the drug for most vaginal operations. In the early period we were being called down a couple of times a week to see patients who were depressed. Now I have found how useful is Dr. Lundy's method of a combination of nitrous oxide with the drug, and I have reduced the amount of pentothal sodium toward the end of the operation and have had no further calls for resuscitation. I should like to ask Dr. Adams about the use of the anesthetic for operations on the head and neck. The more I see of it the less enthusiastic I am. I have discovered that no surgeon is to be trusted to watch the airway properly or to do something about it if he does interfere with it. So far I haven't attempted to use the drug for abdominal surgery when complete relaxation is needed.

DR. ROBERT A. HINGSON, U. S. P. H. S.: I wish to report 10,000 pentothal sodium administrations. They have been administered in a somewhat unorthodox fashion. Because of the shortage of help in our larger marine hospitals we have solicited the aid of nurse anesthetists and medically trained pharmacists' mates. In the latter series of 5,000 cases, administered chiefly by nurses and trained pharmacists' mates, there has been only one anesthetic death, whereas in the first 5,000 cases administered wholly by physicians there were two deaths. Individuals with the background of a nurse anesthetist or pharmacist's mate can be trained to use this technic. We have trained 36 pharmacists' mates who have gone to Coast Guard cutters throughout the North Atlantic, and on occasion these Coast Guard pharmacists' mates have performed magnificently where there was only one physician on a cutter of 150 to 200

men and an anesthetic was needed. We believe that pentothal sodium in their hands is one of the safest forms of anesthesia. We would like to substantiate all of the warnings that Dr. Adams has given. The group at the Mayo Clinic, in introducing this new agent, has always been fair in calling attention to the dangers as well as to the good points. I would urge individuals who report difficulty with this type of anesthetic to go to a clinic where it is being properly used. Only by such dissemination of information can we make final progress. Stimulation of the patient who has been overdosed can be accomplished by administration of 25 mg. of ephedrine in the vein just as promptly as with metrazol.

DR. S. A. SWENSON, Rushville, Neb.: In the hands of an expert there is little danger, although I think one death in 5,000 is rather high. That is about as high as with chloroform. We men out in the country using these methods of experts should use them with due care and with considerable awareness of the danger.

DR. HUGH A. CUNNINGHAM, Milwaukee: I have administered intravenous pentothal sodium 212 times over a period of twenty-six months to a woman aged 27. In the light of the early work on pentothal, this would be strictly contraindicated. This patient has at varying times received all of the sulfonamides. Her lesions were caused by *Bacillus necrophorus*, an anaerobe that travels by way of the lymphatics, leaving a necrotized area or a large abscess. Pentothal, as it was first introduced by Dr. Rovenstine, should not be administered more than every third to fifth day and should then be carefully watched. This patient frequently has had pentothal as often as twice a day, over an extended period of time. Since the thirty-third administration, periodic liver and kidney function tests have been taken. Over the last forty administrations she has demonstrated from time to time from 4 to 12 per cent dye retention in her liver function tests, but on a short rest she replaces this. She still has the disease; we are still using pentothal, so I would like to ask: how often it can be repeated, what changes we should expect, and to how young a patient Dr. Adams has ever given pentothal.

DR. ARTHUR C. McCARTY, Louisville, Ky.: The Surgeon General of the Army has directed the medical officers to use greater care in the administration of pentothal sodium to avoid untoward results. A directive has been issued saying that pentothal must be limited to minor cases, shall not be used for operations around the head and neck, particularly when there is danger of hemorrhage into the respiratory passages when there is infection in that neighborhood, and in brain operations, prolonged operations, it shall be used rarely or with great caution. This is no news to experienced anesthetists, but obviously difficulties have arisen as the result of the use of pentothal in these circumstances. I am situated in a general hospital which is a neurosurgical center. We have found pentothal useful. One of the discussers mentioned the difficulty of controlling the airway in operations about the head. I have found it useful to pass an intratracheal tube, with the patient under pentothal anesthesia, cocaineizing the throat sometimes. At other times I use a local anesthetic in the lubricating solution; sometimes I use no supplementary anesthesia. I have found that the use of an intratracheal tube is of great assistance in controlling respiration in head operations, and it makes these much simpler and cuts down many of the complications that might otherwise arise from respiratory obstruction and from hemorrhage of the respiratory passages.

DR. HERMAN LENOWITZ, Maywood, Ill.: At a government hospital we have given 5,000 pentothal anesthetics with one death attributable to the drug. The man was in partial congestive failure before the anesthetic was given. We have used pentothal extensively for lesions about the head and neck and for genitourinary work as well as for orthopedic surgery. We do not hesitate to use pentothal in extensive prolonged operative procedures over a long period of time. We have

used as little as a few cubic centimeters of a 2.5 per cent solution and as much as 4.5 Gm. We frequently have occasion to work about the larynx. These are our troublesome problems, because the bleeding has to be controlled in some way, and we have found that by introducing an intratracheal tube and giving oxygen with a catheter the patient does very well. This is particularly true in total glossectomies and in lesions of the nasopharynx. We have discarded the use of the 2.5 per cent sodium pentothal solution. We find a weaker solution is just as effective and that it gives the same type of anesthesia. The control is better, the toxicity is less and the reactions of the patient are very few. We have modified this solution to 1:250, 1:500 or 1:1,000, depending on the purpose for which it is being used. We have used it in conjunction with a spinal anesthetic for an apprehensive patient who wants to be asleep, although we find that spinal anesthesia is the procedure of choice in this particular case. We use it extensively in amputations, in genitourinary work and in thoracic surgery. We do not use it in pneumonectomies or lobectomies, but in thoracoplasties we find it to be a desirable agent.

DR. STUART C. CULLEN, Iowa City: I want to ask Dr. Adams if he concurs in the opinion, expressed by a previous discussor, that the administration of pentothal (which includes a knowledge of the care of the airway, judgment as to its use in certain situations and an ability to remedy untoward reactions promptly and efficiently) is so simple that this agent and technic can be turned over to nonmedically trained persons for unsupervised use.

DR. R. CHARLES ADAMS, Rochester, Minn.: Dr. McNeal's question about the use of pentothal for surgery about the head and neck has been answered by Dr. McCarty. I agree with what he had to say. For extensive operations about the head and neck intratracheal anesthesia carries a wider margin of safety and control, particularly in regard to the airway, than does intravenous anesthesia. When it is necessary to maintain fireproof conditions, an intratracheal tube may usually be inserted under intravenous anesthesia without undue difficulty. This is facilitated by spraying the pharynx and glottic region with a local anesthetic solution. I have no argument with those who wish to use pentothal sodium as a sole anesthetic in abdominal surgery. I have not been able to provide most surgeons with the relaxation they prefer without using excessive doses of pentothal sodium and causing undue respiratory depression in most cases. Under these circumstances I feel that the advantages of intravenous anesthesia are outweighed by the disadvantages. However, by supplementing intravenous anesthesia with an abdominal wall or intercostal block, satisfactory anesthesia can be obtained without undue depression of respiration and without using a large dose of pentothal. In regard to the use of intravenous anesthesia for children, I feel that we have much better and more controllable anesthetics for children under 10 years of age than pentothal sodium. Dr. Cullen's question as to how long it takes to attain judgment in selecting suitable cases for pentothal anesthesia and when you can and when you cannot control the airway is apropos. I believe that its intelligent application requires considerable skill and experience not only with intravenous anesthesia but with other types of anesthesia for the many and varied types of operations. It would be hazardous to entrust the administration of pentothal sodium under these circumstances to nonmedically trained persons, particularly if they were not carefully supervised. To illustrate this point I will cite the case of a boy of 15 years with a little fibroma in his postnasal region for implantation of five or six radon seeds. Pentothal sodium was used, and after the operation had been completed the boy became cyanotic and stopped breathing. I visualized his glottis with a laryngoscope and pulled a large clot of blood out of the trachea, which had resulted in a complete respiratory obstruction and which would have caused his death if I had not had the equipment to remove it promptly.

CLINICAL OBSERVATIONS IN TYPHUS FEVER

WITH SPECIAL REFERENCE TO THE
CARDIOVASCULAR SYSTEM

MAJOR THEODORE E. WOODWARD

IN COLLABORATION WITH

MAJOR EDWARD F. BLAND

MEDICAL CORPS, ARMY OF THE UNITED STATES

This study was undertaken principally to observe the various physiologic changes occurring in typhus fever with special attention directed to the status of the general circulation. Previous descriptions of the disease frequently refer to cardiac collapse, cardiac failure or cardiac weakness and in areas where typhus is prevalent it is almost a routine procedure to administer cardiac stimulants in the form of digitalis, ouabain or perhaps some other substitute. Likewise, in certain sections cardiac drugs are given because of the extremely weak and toxic appearance of the patient with the thought in mind that these cardiac tonics will improve the circulation. The latter is not in accord with the actual physiologic effect of digitalis, and Luten¹ has shown that the only clinical indication for digitalis and drugs with digitalis-like action is "evidence of cardiac failure" and in certain arrhythmias. In our study there was no clear indication for cardiac stimulants and hence they were not employed. Actually there was evidence to suggest that a possible harmful effect might ensue from their use.

On the other hand little mention has been given to "peripheral circulatory weakness" with minimal stress directed toward its explanation or to this factor playing the major role, exclusive of the heart per se, as the real cause for this very apparent circulatory deficiency. Wolbach, Todd and Palfrey² mention 4 fatal cases showing irregular pulse which until death demonstrated no evidence of cardiac insufficiency. The very pathology of typhus suggests an overwhelming generalized involvement. The rickettsias invade the entire circulatory tree, causing swelling of the endothelial cells with actual thrombosis of the smaller and occasionally larger vessels. More commonly the changes are in the smaller vessels, causing multiple minute foci of necrosis (figs. 1 and 2). The typhus lesion has been especially well demonstrated in the skin, liver, kidney, cardiac and voluntary muscle and brain but also in every organ of the body.

Recent progress in handling the various forms of surgical shock³ indicates an increase of capillary permeability which alters the electrolytic composition of the blood, lowers the osmotic pressure by escape of plasma proteins into the tissues (lowering blood volume) and finally, when circulatory failure is established, creates a vicious cycle with resulting tissue anoxia accentuating the capillary damage. In typhus one does not have to

Major Woodward is attached to the United States of America Typhus Commission. Major Bland is assistant chief of the medical service, 6th General Hospital.

Capt. Daniel S. Ellis, M. C., of the 6th General Hospital, assisted in much of the clinical study. Major Eugene R. Sullivan, M. C., and Capt. Sedwick Meade, M. C., of the 6th General Hospital Laboratory, aided to a considerable extent in the technical investigation.

2. Wolbach, S. B.; Todd, J. L., and Palfrey, F. W.: *Etiology and Pathology of Typhus*, Cambridge, Mass., Harvard University Press, 1922.

3. Moon, V. H.: *Shock: Dynamics, Occurrence and Management*, Philadelphia, Lea & Febiger, 1942. Blalock, A.: *Principles of Surgical Care, Shock and Other Problems*, St. Louis, C. V. Mosby Company, 1940.

presume that there is capillary damage, because this is evident since the endothelial cell is the site of the specific lesion. The present study was outlined to evaluate the state of the circulation, to clarify the status of the "typhus heart" and to investigate the physiologic changes in the blood of severely ill patients.

PLAN OF STUDY

A ward was established in French Morocco to which patients were admitted as early in the illness as possible, regardless of prognosis. Thirty were studied, representing either severely or critically ill patients. After proper delousing procedures, base line studies were performed, following which the patient was put on a general supportive program. Along with the clinical studies fluid intake and output was observed with a check as to weight loss during the illness. Routine biopsy of the typical skin lesions was performed for

Fig. 1.—Skin biopsy of a typhus lesion on the second day of exanthem. It shows swelling of the endothelial cells and a well defined perivascular cellular reaction (Giemsa.)

future pathologic study. The diagnosis was established by (1) clinical findings, (2) Weil-Felix agglutination, (3) complement fixation with egg antigens,⁴ and in certain instances (4) virus isolation in guinea pigs.⁵

⁴ Castaneda, M. R.: Studies on the Mechanism of Immunity in Typhus Fever, *J. Immunol.* 31: 285, 1936. Bengston, L., and Topping, N.: Complement Fixation in Rickettsial Diseases, *Am. J. Pub. Health* 32: 48, 1942. Plotz, H.: Complement Fixation in Rickettsial Diseases, *Science* 87: 20, 1943.

⁵ It is universally accepted that a positive proteus (OX 19, OX 2, OX K) agglutination in rising titer is definite evidence of a rickettsial infection. In certain localities where several such diseases occur (North Africa with epidemic and murine typhus along with *fièvre boutonneuse*) clinical differentiation may be difficult and other laboratory procedures are necessary. The three fevers mentioned may occasionally give proteus agglutination with the OX strains, in which instance complement fixation helps. For example, serum from a case which "fixes" complement using a specific epidemic antigen is more than pre-emptive evidence of classic European typhus, whereas fixation with a specific murine antigen in high titer indicates murine infection. Serum from a case of *fièvre boutonneuse* produces negative results with murine and epidemic antigens but "fixes" complement using a Rocky Mountain spotted fever antigen (which coincides with the known antigenic similarities of these strains). An antiserum with pure *Rickettsia conorii* (*fièvre boutonneuse*) would be an additional aid in diagnosis.

CLINICAL OBSERVATIONS

Cardiorespiratory.—Examination of the heart revealed no enlargement, and this was confirmed by x-ray study in 12 instances. Heart sounds were commonly distant, being frequently masked by respiratory sounds, and in this series gallop rhythm and cardiac arrhythmias were consistently absent. In none of the cases was there engorgement of the neck veins or evidence of liver enlargement. Ascites was not observed. Cyanosis of the lips, ears, fingers and toes was a fairly common sign. Peripheral edema was noted in 1 instance on the dorsum of the feet, at which time the patient showed a lowering of plasma proteins (4.98 Gm. per hundred cubic centimeters), a secondary anemia, without concomitant signs of cardiac failure in the veins, liver or lungs.

The pulse at the height of illness was thready, of poor quality and usually in the neighborhood of 110 to 120. Patients responding poorly often had pulse rates of 130 or more and even at times imperceptible by palpation. Several patients with completely adequate circulation showed slightly increased rates even at the time of discharge, whereas in 4 cases a mild bradycardia of 48 to 60 occurred late in the second week of illness.

The pulmonary picture was dominated by varying grades of tracheobronchitis from a true bronchitis to a bronchiolitis. Circulatory congestion of the lung was not observed. Rhonchi and coarse, moist, sibilant and sonorous rales were frequently heard throughout both lungs without percussion impairment. Coughing, often persistent and bothersome, was for the most part non-productive, since the patient was often too weak to expectorate. Numerous sputum examinations revealed mixed flora with no one organism predominating. When these changes in the lung occurred along with the general circulatory picture of collapse, the patient appeared just as comfortable in the recumbent as in the sitting position, contrary to one suffering from pulmonary congestion of cardiac origin.

Blood Pressure.—Daily blood pressures indicated generally a definite drop of both systolic and diastolic readings, in some instances figures as low as 68/40 existing for variable periods. The lowered blood pressure often persisted well into convalescence, a normal figure being noted in many cases six weeks after illness when a follow-up examination was made. Occasionally normal levels were regained soon after desferoxamine of the acute illness, while a minority sustained adequate tension throughout the illness. Diastolic readings were consistently low, ranging from 40 to 60.

Peripheral circulatory weakness caused by lack of blood vessel tone and low blood volume, rather than cardiac insufficiency per se, most likely accounts for these changes. Aytzin⁶ observed this loss of vascular tone because epinephrine hydrochloride when instilled in the conjunctivas of typhus patients did not alter the vascular congestion whereas when instilled in normal conjunctivas prolonged paling occurs.

Venous Pressures.—Venous pressure was measured during the first and second week of illness, during early convalescence and in many cases daily and before and after intravenous therapy. Readings were consistently low, ranging from 2 to 12 cm. of water, the average of all cases being 8 cm. of water. In 1 case a preliminary reading of 20 cm. was observed on admission. This man was decidedly spastic and irrational, and it is

⁶ Aytzin, A. P.: Conjunctival Exanthem in Spotted Typhus, *Arch. Path.* 36: 158 (Aug.) 1943.

probable that this apparent initial elevation was the result of technical difficulties (spastic muscles) since all subsequent readings were normal and there was no evidence of congestion of the cervical veins or of the liver. The tests were performed frequently when the respiratory signs were prominent. Furthermore, no increase of venous pressure or of pulmonary congestion was observed after the intravenous administration of 1,000 cc. of fluid—a further indication of the absence of any important element of cardiac weakness in these otherwise seriously ill patients.

Electrocardiograms.—Electrocardiograms consisting of the standard limb leads were secured of 24 patients of this series during the most active phase of their disease, usually toward the beginning of the second week. In 4 instances a second tracing was made during convalescence for further study of certain abnormalities previously observed. To supplement this series we had an opportunity during the recent Naples epidemic (1944) to secure records on 14 additional patients also severely ill with typhus. Four of the latter group were in terminal coma at the time records were taken and died two to four hours later.

In general the electrocardiograms exhibited no striking deviations from the normal as regards high grade conduction defects or important T wave changes. However, certain relatively minor abnormalities were recorded with sufficient frequency (in 18 of the 40 patients, or 45 per cent) to warrant a comment: 1. Low voltage of the QRS complexes in all of the standard limb leads of less than 5 mm. deflection was recorded in 7 instances. In 2 additional patients there was slurring of the QRS complexes up to 0.10 second, but in no instance was well defined intraventricular block observed. 2. A delay in the auriculoventricular conduction time of slight degree (0.20 second or more) occurred in 6 patients, but in only 1 of these was the delay as much as 0.23 second. 3. Abnormally low T waves of less than 1 mm. in all leads were noted in 5, and in 2 additional patients there was depression of the ST interval of more than 1 mm. in all leads. 4. Auricular fibrillation with a relatively slow ventricular rate of 70 was recorded in a moribund patient who died two hours later. None of these patients had been taking digitalis or allied drugs.

These results are in accord with the clinical findings, which indicated that no serious disturbance of cardiac function per se appeared to be responsible for the circulatory phenomena previously discussed. A return to normal in the 4 patients in whom subsequent tracings were made during convalescence suggests that these minimal and transient electrical abnormalities are probably comparable in patients severely ill with pneumonia, with typhoid and with uremia.

Röntgenography.—We were unable to take routine films on every patient because of technical difficulties, but of the 12 examined cardiac enlargement was not encountered. One patient with a well sustained mitral systolic murmur presented slight prominence in the region of the pulmonary conus. This murmur was heard at the onset and was masked slightly during the illness by the pulmonary picture of tracheobronchitis, but during convalescence and eight weeks after departure from the hospital it was still present with radiation toward the axilla. Electrocardiographic changes in this man of slight left axis deviation and a PR interval of 0.22 second suggested a concurrent rheumatic infection. In most of the films of this as well

as of other patients the pulmonary fields were compatible with diffuse bronchitis and in 2 there were areas of localized infiltration of bronchopneumonia, but in none was there evidence of circulatory congestion.

CLINICAL PATHOLOGIC FINDINGS

Blood and Hematocrit.—In severe cases there was a drop in the red blood count of 1 million or more. Usually on admission the count was within normal limits, at which time the patient was severely dehydrated. Once hydration was accomplished, the red cells ranged from 2,500,000 to 3,700,000. The volume of cells ranged from 23 volumes per cent to 42 volumes per cent with the mean figure about 32 volumes per cent. All of the more severe cases presented, during the acute phase of illness, a volume of cells much less than normal. White blood cell counts were more consistently on the lower edge of normal (4,000 to 6,000), but in some cases counts of over 10,000 were found. Patients with pyogenic complications showed the higher counts. Differential smears were not remarkable.

Serum Protein.—A drop in the total protein level was not as striking as the corresponding deficiency of the

Fig. 2.—Typhus nodule in cerebral tissue of a fatal case. The perivascular elements are pronounced and the vessel is occluded by endothelial swelling and thrombus. (Giemsa.)

albumin fraction. The overall average for total protein was 5.2 Gm. per hundred cubic centimeters. Fibrinogen determinations were not done, but a drop of albumin and globulin elements was almost consistent and in a large percentage of patients the albumin:globulin ratio was reversed with albumin as low as 0.9 Gm. per hundred cubic centimeters. These findings were pronounced in the second week of disease and persisted well into convalescence. The smaller albumin molecule may well escape into the tissues because of altered capillary permeability, resulting in the edema which is occasionally observed. Several factors account for the reduced total protein figures; (1) lack of adequate protein intake, (2) altered hepatic function and (3) the available protein reserve being quickly expended by the disease process.

Chlorides.—This feature is reported by Julliard⁷ and was not adequately investigated in this study save for blood levels which were reduced and which could be elevated by oral and parenteral administration of

7. Julliard, J. and Henaff. Troubles du métabolisme hydrochlorure au cours des typhus épidémique et murin, Rev. ser. de san. mil 110: 197, 1939.

chloride. Blood levels varied from 70 milliequivalents per liter to 110 milliequivalents per liter. More work is needed to determine the persistence of this abnormality along with tissue analysis to clarify the fate of the chloride. Julliard has found the urine chloride low from early in illness and persisting until the first week of convalescence. This observer reports normal and urine chlorides in the murine typhus case.

Carbon Dioxide Combining Power.—In association with the chloride deficit, a state of alkalosis existed in these patients and the semicomatose cases often showed figures of 90 volumes per cent. In those less severely ill this determination was within normal limits, the lowest reading observed being 50 volumes per cent.

Urinalysis.—The urine evidenced few abnormal features. The specific gravity was normal, indicating that the kidney was able to concentrate well. In the first and early in the second week variable amounts of albumin appeared, never exceeding 2 plus amounts with the Robert technic. Frequently there was no albumin whatever. The p_H of urine ranged from 7.0 to 8.0. There were few cellular elements noted microscopically, with an occasional white cell and a very occasional red blood cell. Casts were almost never seen. Various forms of crystals appeared, the more common being calcium and amorphous and triple phosphates. Findings for proteose were inconsistent and urobilin was rarely elevated above normal, which indicates the absence of any active red blood cell destruction. Oliguria, commonly seen early in the illness in spite of an intake of 4,000 to 5,000 cc., often persisted until the middle of the second week, when a sudden diuresis frequently appeared. This fact alone is ample evidence of the profound state of dehydration and the need for active corrective measures.

Nonprotein Nitrogen.—Severely ill patients, on admission, without previous supportive therapy consistently showed an elevated nonprotein nitrogen, and early in the second week 90 mg. per hundred cubic centimeters was not uncommon. Comatose patients always presented this elevation but, once hydration was accomplished, chloride administered and urinary output sustained, this azotemia could be corrected, and in some instances a nonprotein nitrogen of 90 mg. per hundred cubic centimeters was lowered to 30 mg. per hundred cubic centimeters in three to four days. In less severe cases the nonprotein nitrogen was not remarkable.

In view of these findings it is difficult to explain the azotemia on a renal basis. Extrarenal azotemia is commonly seen in dehydration alone, but in typhus there are additional factors. The circulation is poorly sustained, so that reduced glomerular filtration pressure accompanies reduced arterial tension. The specific pathologic lesion causes widespread protein breakdown in the many minute areas of destruction in the muscle, brain and other tissues. Likewise a certain amount of hepatic dysfunction would tend to load the circulation with an excess amount of nitrogen waste. A small amount of endothelial damage is found in the typhus kidney, but hardly enough to explain the suggested renal embarrassment. Exhaustive renal function tests would be of immense value in evaluating the typhus kidney, to determine whether the azotemia is entirely of renal or extrarenal origin.

Spinal Fluid.—Lumbar puncture was done routinely. From the sixth to the tenth day of illness meningismus was commonly so pronounced in certain patients as to suggest a meningeal infection. The absence of Kernig's

sign was of great aid in the clinical differentiation. In agitated patients pressures of 240 to 260 mm. of water were seen. Pressures within normal limits likewise existed. In patients subjected to repeat taps the higher readings had returned to normal after five to seven days. Two instances of pleiocytosis were observed, 20 and 80 cells respectively, in each case the predominant cell being mononuclear. The Pandy test rarely showed more than traces of globulin. As previously reported by Blanc,⁸ strain isolations were attempted in those patients with the more pronounced central nervous system symptoms. Virus was not successfully isolated from the spinal fluid in spite of attempts as early as the fifth febrile day. In 1 instance isolation was tried simultaneously from blood and spinal fluid, the former being successful and the latter producing only a non-specific type of temperature curve in the guinea pigs.

Complications.—In this series complications were relatively uncommon. Several patients developed severe tracheobronchitis, with an inability to expectorate properly progressing into a patchy bronchopneumonia. One man developed a bilateral otitis media which in no way affected the progress of the disease. A middle aged woman developed a dry pleurisy which ran an acute course of four days and was otherwise not remarkable. Two women developed unilateral parotitis, 1 having been admitted with this infection. Both received adequate supportive measures of intravenous fluids when an adequate intake by mouth was difficult. In spite of the suggested harmful effects of the sulfonamide drugs on typhus,⁹ small amounts of sulfadiazine were given with the possibility of preventing a bilateral parotid infection, which many times ends fatally. Sufficient urinary output was maintained during this period, and it was felt that little danger from the drug would follow. One of the women (T. B. A.) required surgery for her unilateral parotid abscess, at which time incision and drainage were done, *Staphylococcus aureus* being subsequently cultured. Both she and the other patient made complete recoveries. Phlebitis was seen in 1 case without further complication.

Deaths and Mortality Figures.—Of the 30 patients studied, 2 died. One, a woman aged 73 admitted late in the second week of illness, was hopelessly ill on admission and at the time of her death showed no evidence of cardiac insufficiency and her venous pressure was normal. Autopsy was not permitted. The other patient, a man of 25, died in an overwhelming toxic state with a generalized severe tracheobronchitis, with inability to expectorate mucus. Postmortem examination revealed a normal sized heart (350 Gm.), the lungs showing an early patchy bronchopneumonia with thick, yellowish, tenacious mucus expressed from the bronchi and bronchioles, the latter containing a mixed flora. Throughout the illness this man presented neither venous engorgement, liver enlargement, peripheral edema nor abnormal venous pressures.

In the hospital where this study was performed there were, from the period January to June 1943, 679 cases of typhus with 81 deaths, representing a mortality of 12 per cent. The highest monthly mortality was 15.1 per cent and the lowest 10 per cent. These cases may be considered by our standards to have received inadequate supportive therapy. Our series of 30 cases with 2 deaths represents a mortality of 6.6 per cent. It is

8. Blanc, G.: Recherches sur le typhus exanthématique poursuivies au laboratoire de Nèch d'Avril à Octobre 1913, *Bull. Soc. 14th* extra 9:5, 1916.

difficult to attribute great significance to this lowering, but the assumption that adequate supportive therapy was a factor may be safely made.

SUPPORTIVE PROGRAM

The general supportive measures employed in these cases and suggested as a rational approach for support of the severe typhus case are as follows:

1. *Nursing*.—Attention to the mouth, care for the prevention of gangrenous skin lesions and the frequent changing of position to facilitate expectoration and to prevent pulmonary complications are most important. The use of sedatives for the agitated case is indicated.

2. *Adequate Fluid Intake*.—At least 4,000 cc. should be given daily, when possible by mouth. In the usual case, in spite of the extreme thirst, this amount may not be taken and the remainder may be given intravenously. This procedure is indicated when there is evidence of a poorly sustained circulation manifested by low arterial tension, a fast thready pulse and cyanosis, along with the evidence given by hematocrit and other studies. Large amounts of subcutaneous fluids are administered with difficulty to the typhus patient and tend to the development of soft tissue edema. Concentrated glucose (50 per cent) has been found useful for patients with oliguria and anuria.

3. *Blood Plasma*.—A small number of patients have been given transfusions of dried blood plasma and the effects have been excellent for supporting the circulation. This is a valuable means for restoring the depleted protein level.

4. *Chlorides*.—The ammonium and sodium salt have been used to improve the hypochloremia. From 2 to 4 Gm. of ammonium chloride was used along with 3 to 5 Gm. of sodium chloride. The ammonium salt is preferable.

5. *Diet*.—In severe cases in which efforts of high caloric drinks by mouth are not feasible, an indwelling stomach tube is of benefit. Nourishing protein and carbohydrate foods may be administered in this fashion to give considerable support to the patient. Vomiting is seen in the early stages of typhus but rarely during the actual course.

6. *Digitalis*.—This drug and other cardiac stimulants were not indicated in a single instance in this series, and we suspect that the indiscriminate use of these for patients as seriously ill as ours may occasionally be actually harmful. In the presence of congestive heart failure or auricular fibrillation with an uncontrolled ventricular rate the cautious use of digitalis combined with diuretic therapy (in the former instance) would seem a desirable adjunct to the general measures outlined.

7. *Sulfonamide Drugs*.—Small amounts were given in cases complicated by purulent infection, during which time satisfactory urinary output was maintained. No ill effects were observed.

8. *Iron*.—This is useful in convalescence for combating the secondary anemia.

SUMMARY OF FINDINGS

When the various clinical pathologic changes occurring during severe typhus are summarized, a fairly definite physiologic picture is evident. The patient is acutely ill and very toxic, with a significantly low arterial tension and a labile pulse. Usually unless actively supported the patient becomes dehydrated, the red cells decrease and plasma proteins fall with a con-

siderable loss of the albumin fraction indicating a reduced colloidal osmotic pressure. All factors indicate a drop of blood volume with the pattern of hypoproteinemia, hypochloremia and hemodilution without blood destruction. The unstable circulation results in lowered glomerular filtration pressure, and hence oliguria and anuria occur. The kidney, partially damaged by the specific pathologic condition and called on to eliminate an increased amount of nitrogenous waste, is unable to function normally unless adequately supported by fluids. Lowered blood volume means less adequate filling of the heart during diastole and hence lowered cardiac output. Each beat of the heart is less efficient. The use of cardiac stimulants under these conditions is ineffectual, but when the volume of the blood is restored the organ can operate more efficiently. For this reason it appears that cardiac drugs, except perhaps in exceptional instances, are contraindicated in typhus and once the blood volume is restored there is no indication for specific heart therapy unless unmistakable signs of cardiac failure exist, a condition that has not been observed in this series. Wolbach and his associates¹⁰ have demonstrated the typhus lesion in heart muscle, the kidney, and for that matter in every organ of the body with relatively few exceptions. However, the degree of both cardiac and renal pathologic changes is in no way out of proportion to the changes occurring elsewhere, and from our clinical studies it seems unlikely that cardiac failure as such is often a significant factor in the outcome of the fatal case. It is not intended to convey the impression that the treatment of typhus is merely an automatic procedure and once blood chemical and abnormal physiologic processes are corrected that all is well. This is far from true. In typhus we are well aware of the central nervous system involvement with the profound effect of the rickettsial toxin¹⁰ not only on the brain but throughout the entire system. Our studies indicate that in the severe typhus case the chance for recovery is greater by observing and attempting to counteract the various clinical pathologic alterations.

CONCLUSIONS

From a detailed clinical laboratory study of 30 patients with severe epidemic typhus with special reference to the circulation, it has been shown that:

1. The altered circulation state, owing probably to widespread in severe cases, consists primarily of an inadequate circulating blood volume, hypoproteinemia (especially the albumin fraction), hypochloremia, hemodilution without blood destruction and an azotemia.

2. The circulatory collapse frequently encountered under these conditions is primarily of peripheral origin.

3. General supportive measures to increase the circulating blood volume are most beneficial.

4. Cardiac drugs (digitalis and allied preparations) are probably of benefit only in exceptional cases with clear evidence of congestive heart failure. This was not encountered in this study.

5. Further investigation is needed to clarify:

- (a) The blood electrolytes and tissue analysis to determine the fate of chloride.
- (b) Carbon dioxide combining power and the general alkali reserve picture.
- (c) Blood volume studies with the use of both whole blood and plasma in support of the reduced volume.

REPORT OF CASES

CASE 1.—A youth aged 19 was admitted on the fifth day of his illness with a severe headache and an ill defined pink macular rash on the trunk and proximal parts of the extremities. There were coarse rales and rhonchi in the lungs and a normal cardiac contour without venous engorgement, gallop rhythm, palpable liver or peripheral or sacral edema. The spleen was

easily felt. Until the eighth day of illness he was not severely ill but on that day the headache was more intense and he developed definite and pronounced cervical rigidity, with a negative Kernig's sign. He became completely irrational but would take fluids well. In view of his low blood proteins and a circulation not well sustained (tension ranging from 95/52 to 78/40) he was given transfusions of dried blood

Fig. 3.—Tracings in case 1: A, on eighth day of severe typhus, showing low voltage of QRS complexes and a PR interval of 0.19 second. B, eighteenth day, during convalescence, showing normal voltage of the QRS complexes and a lessening of the PR interval to 0.15 second.

plasma of 250 cc. daily for four days along with an intake of 4,000 to 5,000 cc. of fluids orally. The urinary output was sustained throughout the illness on this regimen, along with the chloride mentioned previously. The rash was completely faded on the eleventh day. The mental lethargy persisted until the thirteenth day, with the temperature falling by lysis on the

fourteenth day. During the illness the patient lost 16 pounds (7.3 Kg.). X-ray examination showed the heart and lungs normal. An electrocardiogram on the eighth day of illness showed a low voltage, which was normal on a recheck tracing on the eighteenth day. The PR interval during the acute illness measured 0.19 second but in the subsequent tracing had lessened to 0.15 second (fig. 3 A and B). The diagnosis was confirmed by a rising titer of the Weil-Felix agglutination along with a positive complement fixation with an epidemic antigen. The clinical pathologic studies are given in table 1.

CASE 2.—A man aged 25, admitted on the sixth day of illness, was irrational and complained of a severe headache. There had been a slight cough from the onset of illness, which was present on admission. Dehydration was pronounced. There was a petechial type rash on the trunk, upper arms and thighs. The tongue was very dry, red and thickly coated. The conjunctivas were much injected, along with considerable suffusion of the eyes. The neck was decidedly stiff, with a negative Kernig's sign. The lungs were clear. The heart was normal without signs of cardiac embarrassment. The blood pressure was 84/60, the pulse rate 120. The liver was not enlarged. On deep palpation the splenic tip was felt. Following several days of an agitated state he developed severe mental lethargy, which persisted until the eleventh day. On this day he developed a bilateral otitis media. From the seventh to the tenth day there were spasmodic bouts of hiccuping, at which time the nonprotein nitrogen was elevated. The patient took orally from 4,000 to 5,000 cc. of fluids, supplemented when necessary by intravenous glucose-saline solution. Concentrated glucose (50 per cent) was given intravenously to help sustain the urinary output. Supplemental chloride was likewise administered orally. The cough, although not too bothersome, was present for ten days, being nonproductive and associated with rhonchi

Complement fixation with an epidemic egg antigen.

and coarse rales. At no time were there signs of cardiac weakness. Slight edema on the dorsum of both feet was noted on the eleventh day of illness, at which time there was a reversal of the albumin:globulin ratio. The patient was clinically improved and regarded as "safe" on the twelfth day, when he was able to eat and perform voluntarily. The rash was completely faded on the thirteenth day, disappearing terminally on the legs. An electrocardiogram on the eleventh day showed normal voltage. The spinal fluid pressure on the seventh day was 230 mm. of water with 2 lymphocytes. A repeat tap on the seventeenth day revealed a pressure of 40 mm. of water, which was clear with 4 cells.

CASE 3.—A woman aged 25, Arabian, admitted on the eighth to the ninth day of illness in a severe condition, had a unilateral parotitis and a full blown petechial type rash of the usual distribution. She was dehydrated and had a dry filthy mouth and heavy brown coating on the tongue. The right parotid gland was diffusely enlarged, very tender and nonfluctuant. Flexion of the neck was moderately limited, the patient being in an agitated, moderately delirious condition. There were no signs of cardiac enlargement or failure. Occasional rhonchi were heard in the lungs. The blood pressure on admission was 94/72. The spleen was palpable and moderately firm. The patient was given the usual supportive care. The spinal fluid was found to be under normal pressure, with normal dynamics and clear fluid. Venous pressures on admission and throughout her illness were normal. The rash persisted until the fourteenth

day, when only faint pigmented spots remained. The agitation and delirium remained until the thirteenth day, but throughout the illness thirst was constant, so that the patient was able to take adequate oral fluid. She was given small amounts of sulfadiazine, with an initial dose of 3 Gm. and 2 Gm. daily, with the possibility of preventing a bilateral parotid infection, which would probably have resulted fatally. *Staphylococcus aureus* was subsequently cultured from this infection, since a fluctuant abscess was incised and drained on the seventeenth day. The patient made a complete recovery but after developing a phlebitis, late in convalescence, of the right femoral vein when she was under observation in a surgical ward. The course of the latter was uneventful. An electrocardiogram on the tenth day of illness showed the same low voltage with the PR interval 0.18 second. The urine throughout the illness was normal other than the presence of an abnormal amount of proteose present at the height of the parotid infection. Other findings are given in table 3.

CASE 4.—A white woman aged 73 was admitted on the twelfth to the thirteenth day of illness with pronounced delirium and in an almost completely comatose state. She had a petechial type rash, which was generalized and partially faded on pressure. There was dehydration, with a very dry mouth. Showers of moist rales and coarse rales were heard throughout the lungs, with a partially impaired percussion note posteriorly. The heart was not grossly enlarged, and the liver and spleen were not palpable. Gallop rhythm, venous engorgement, peripheral and sacral edema were absent. There was pronounced cervical rigidity. The respirations were noisy, shallow and rapid. She was obviously regarded as a critical case and was observed as a base line case since she was receiving cardiac and other stimulants by hospital authorities. A severe cough was nonproductive, and the tracheal and bronchial secretion was readily heard. Death came on the third day of hospitalization, and her case is presented because of the interesting physiologic changes. Venous pressure before death was 11.2 cm. of water with no visible evidence of cardiac decompensation. Unfortunately autopsy was not permitted. Other findings are given in table 4.

Clinical Notes, Suggestions and New Instruments

TICK BITE PYREXIA

LIEUTENANT COLONEL ISIDORE A. FEDER
MEDICAL CORPS, ARMY OF THE UNITED STATES

From May 2 to June 25, 1943, during Tennessee maneuvers, approximately 2,600 patients were admitted to the wards of our evacuation hospital. Hundreds of these patients presented dermatologic evidence of having been bitten by ticks. The present illness of most of these soldiers was in no way related to the tick bites. Many had symptoms which could readily be attributed to secondary complications of the tick bites, such as dermatitis due to local irritation and scratching, cellulitis, lymphangitis and lymphadenitis resulting from secondary infection. Seven patients were proved to have contracted tularemia, 3 showing a typical clinical course of this disease, the other 4 recognizable only by subsequent diagnostic titers of their serum in agglutinating *Pasteurella tularensis*.

A smaller group of patients was admitted whose essential complaint was fever, with or without chills. Associated symptoms included anorexia, malaise, headache and occasionally abdominal pain and vomiting. Physical examination was essentially negative except for the discovery of one or more engorged ticks attached to the skin. The only positive laboratory finding in 1 of the cases was a moderate increase in the percentage of the polymorphonuclear cells. Removal of the engorged ticks resulted in subsidence of the temperature and complete relief from the associated symptoms in from twelve to thirty-six hours. Further observation and subsequent serologic studies failed to reveal evidence of the development of any of the specific and recognized tick borne diseases. The

discharge diagnosis for these patients read "fever, simple, caused by tick bite." For the purpose of this article I have termed this condition "tick bite pyrexia" to differentiate it from the many other pathologic states which have been grouped under the heading "tick fever." The latter name has been used to cover a multitude of conditions. Nuttall¹ expressed his opinion many years ago that this name has lost its significance and should be dropped from our nomenclature.

The following are 5 illustrative summaries of the group of cases which came under observation for this syndrome. (All temperatures were taken orally.)

CASE 1.—A soldier was admitted May 7, 1943 with complaints of fever and pain in the abdomen of two days' duration, slight headache and moderate vomiting. Examination revealed slight tenderness in the right lower part of the abdomen. The skin showed signs of numerous tick bites. Two engorged ticks were found embedded in the right axilla. The admission temperature was 104 F. Blood and urine examinations were normal. The ticks were removed by touching a lighted cigaret to their caudal ends. That evening the temperature had fallen to 100.6 F., the following morning to 99 F. and for the next three days remained at a normal level. Coincident with the fall in temperature there was a subsidence of the complaining symptoms and the patient was discharged to duty on May 10.

CASE 2.—A soldier was admitted during the evening of May 8, 1943 with a history of fever, chills, generalized pains and vomiting of one day's duration. The temperature on admission was 104.6 F. Physical examination disclosed only slight lower right rectus muscle spasm. The total white blood cell count was 7,400 with 88 per cent polymorphonuclears. The following morning inspection disclosed an engorged tick attached to the right buttock. The tick was removed. The temperature remained elevated to 102 F. that day, but on the next morning it reached normal, where it remained for the next three days. There was a complete amelioration of the symptoms coincident with the fall in temperature. The soldier was discharged to duty on May 12.

CASE 3.—A soldier was admitted May 10, 1943 with complaints of fever, headache and generalized pains of one day's duration. Examination was essentially negative except for the presence of an engorged tick attached to the skin in the region of the right flank. The temperature on admission was 102.8 F. The tick was not removed. On the following day the temperature was still elevated to 102 F. The tick was now removed. Twelve hours later the temperature had fallen to 98.8 F. and remained within the normal range for the next three days. The patient was discharged to duty on May 14.

CASE 4.—A soldier was admitted May 11, 1943 with complaints of fever, chills, headache and backache of two days' duration. He stated that he had removed many ticks which had been attached to his skin. Physical examination was negative. The temperature was 101.4 F. The temperature subsided spontaneously and remained normal for thirty-six hours. On the evening of May 13 the temperature was again found to be elevated to 102.6 F. Reinspection of the skin disclosed an engorged tick embedded in the left axilla. The tick was removed. Thirty-six hours later the patient felt well and the temperature subsided to normal, where it remained for the following three days. The patient was discharged to duty on May 17.

CASE 5.—A soldier was admitted May 15, 1943 with complaints of fever, headache and malaise of one day's duration. He stated that he had removed 27 ticks from his body. Examination disclosed 2 engorged ticks embedded in the abdominal wall. An admission temperature was not recorded. The ticks were removed. About eight hours later the temperature was noted to be 97.2 F. and the patient stated that he felt perfectly well. He was discharged to duty on the following day.

COMMENT

Ticks are most prevalent during the months of May, June and July. All of our cases of tick bite pyrexia were observed during May.

1. Nuttall, G. H. F.: *Parasitology* 4: 88-93 (June) 1911.

The role of the tick in the transmission of specific disease processes has long been definitely established. The tick may serve as a simple carrier and mechanically transfer the disease agent, or it may furnish the site where the parasites grow or multiply during their residence in this vector. Thus the tick has been incriminated in the transmission of tularemia, relapsing fever, Rocky Mountain spotted fever and the allied group of diseases.

It has also long been felt that ticks may serve as direct agents of disease. An ascending paralysis beginning in the legs and occasionally fatal in its outcome, termed "tick paralysis," has been frequently reported in the more recent literature. Strong² states that it is believed to be caused by a venom secreted by the salivary glands of the tick during the period of rapid egg development. Abbott³ feels it is highly improbable that the cause of the paralysis lies with either a virus or a bacterium. It is more plausible that either a toxin or venom may be the underlying factor. The rapid disappearance of paralysis following removal of the ticks seems to confirm this hypothesis.

The rapid subsidence of the temperature and amelioration of symptoms when the engorged, embedded ticks were removed in our cases suggest a similar causative factor in the development of tick bite pyrexia. One would hardly expect such rapid recovery if the fever was infectious in origin. It is more likely that some toxic substance injected by the tick as it takes its blood meal is the factor responsible for the development of the symptoms. That the ticks have been attached for a prolonged period of time is evidenced by their engorgement. Not all ticks carry this fever producing toxin, for only few of the soldiers with attached ticks developed symptoms of this condition. The few ticks which we were able to examine proved to be females of the genus *Dermacentor*. Mackie⁴ states that "apparently *Dermacentor* ticks, in addition to producing tick paralysis, may in certain individuals cause a picture of chills and fever following tick bite." The exact manner in which the toxin or venom is produced in the tick is unknown, but it can be postulated, as in tick paralysis, that it resides in the female, is associated with the production of eggs and becomes evident only after the tick is partially or fully engorged.

TREATMENT

A director memorandum June 3, 1943 stated that "there is an indication of the need for preventive control of ticks by all military personnel. In the selection of bivouac sites, tick infested areas should be avoided if possible. Ticks should be removed from the body at least once daily. Careful examination of the body after coming from tick infested areas and on retiring should be routine."

Ticks should be looked for especially on the scalp, neck, axillary and popliteal regions, lower part of the back and the gluteal folds and in the umbilicus. They should be removed intact with a thumb forceps, gasoline or ether or by touching the caudal end of the tick with a hot burned out match or the lighted end of a cigaret. I utilized the latter method. Ticks should never be crushed with bare fingers. The site of the tick bite should be painted with iodine.

SUMMARY AND CONCLUSIONS

1. Tick bite pyrexia appears to be a definite syndrome resulting from the bites of certain ticks.
2. It is presumably caused by a toxin or venom secreted by the female tick rather than by a bacterium or virus carried by it.
3. Removal of the offending tick is followed by a rapid subsidence of the temperature and associated symptoms.
4. Careful examination of the body and removal of all attached ticks is essential for the control of this syndrome as well as for the control of tick paralysis and other specific tick borne diseases.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

During the October 1943 Council meeting it was decided that a status report on the prophylaxis of Hemophilus pertussis infections would be of much value for the physician. Accordingly, Dr. Harriet M. Felton and Miss Cecilia Y. Willard have prepared the following statement, which the Council has adopted for publication. The Council will now consider for inclusion in New and Nonofficial Remedies H. pertussis vaccines prepared according to the method of Sauer or of Kendrick and Eldering or of Harrison and Bell.

AUSTIN E. SMITH, M.D., Secretary.

CURRENT STATUS OF PROPHYLAXIS BY HEMOPHILUS PERTUSSIS VACCINE

HARRIET M. FELTON, M.D.

AND

CECILIA Y. WILLARD, M.S.

PHILADELPHIA

In 1914 the Council on Pharmacy and Chemistry of the American Medical Association admitted pertussis vaccines to New and Nonofficial Remedies on the basis of what appeared at that time to be acceptable clinical evidence. During the next fifteen years these vaccines were used extensively for both prophylaxis and treatment. The reports, however, indicated that the results were not very satisfactory. Therefore in 1928 the Council voted to omit pertussis vaccines from New and Nonofficial Remedies with the close of the longest period for which any one had been accepted, unless new evidence proving efficacy was produced. Reports from different investigators continued to vary and in 1931 the Council¹ recommended that these vaccines be entirely omitted from New and Nonofficial Remedies.

It is interesting to note that in the same year one of the most important advances in the study of the pertussis organism was made. Leslie and Gardner² found that *Hemophilus pertussis* is a uniform species which, when grown on artificial mediums, passes through a series of antigenically different phases. Strains recently isolated from cases of whooping cough were designated as phase I. These strains are virulent for guinea pigs and serologically distinguishable from the variant non-virulent phases. Since this discovery the majority of vaccines have been prepared from freshly isolated cultures, although stock cultures are still used by some workers who claim that the organisms remain in the virulent phase I if they are grown under suitable conditions.³ It is quite possible that the varying reports on the use of the earlier vaccines were due in some measure to the lack of uniformity in antigenicity of the strains used in the preparation of the vaccines.

The reports on the use of the earlier vaccines were difficult to evaluate, owing to the fact that no adequate controls were included in the various clinical studies and that the vaccines used were of many types with poorly established, inadequate dosages. However, since 1933 there has been a succession of more careful clinical studies which seem to indicate that vaccines of greater

efficiency have been prepared. In order to determine the current status of *Hemophilus pertussis* vaccines a summary of the most important of these studies will be presented.

The first encouraging reports on immunization were those of Madsen,⁴ who presented the results of two epidemics, in 1924 and 1929, in the Faroe Islands. The vaccine used was prepared by the Danish Serotherapeutic Institute, Copenhagen, following the introduction of the cough plate method of diagnosis by Chievitz and Meyer.⁵ A forty-eight hour growth of freshly isolated organisms was rubbed into phenolized or formaldehyde treated saline solution to a concentration of 10 billion organisms per cubic centimeter of vaccine. The total dosage was 22 billion bacteria given in three injections at three to four day intervals.

In the first epidemic vaccination was begun after the disease had reached the islands. Here 2,094 children were vaccinated, and there were 627 unvaccinated children of similar age used as controls. The majority of both groups developed the disease, but there were only five deaths in the vaccinated group as compared with eighteen in the control group, or fatality rates of 0.24 and 2.9 per cent, respectively. It was concluded that while the vaccination was of no prophylactic value it greatly reduced the severity and duration of the disease. The records showed that the best results were obtained when the vaccination was completed one week before the onset of the disease.

In the second epidemic vaccination was completed shortly before the outbreak occurred. In this instance prophylaxis was found to be much better. There were 1,832 vaccinated children, of whom 75 per cent contracted whooping cough, but among 446 controls the incidence was 98.2 per cent. The fatality rates were 0.07 per cent and 1.8 per cent, respectively. It was thought that the favorable results were probably due to the fact that the vaccine was made from freshly isolated strains of *H. pertussis* and to the fact that the course of vaccination was completed shortly before the onset of the epidemic. In both epidemics the total number of bacteria in the immunizing dose of vaccine (22 billion) was larger than that used by others at this time (50 million to 3.5 billion).

In 1933 the first significant reports from the United States were published by Sauer.⁶ After obtaining uncertain results with the various commercial vaccines available between 1915 and 1925 he prepared a new type of vaccine, and the results of its use gave definite indication of a more effective product. The preparation of the new vaccine incorporated the principles suggested by Madsen and followed closely the criteria for phase I *H. pertussis* as described by Leslie and Gardner. From five to seven recently isolated, strongly hemolytic strains were used. The culture medium of Bordet and Gengou⁷ was modified to contain human blood instead of horse blood. A forty-eight hour growth of the organisms was scraped from the surface of the medium and suspended in phenolized saline solution in a concentration of 10 billion organisms per cubic centimeter of vaccine. It was found that the total dosage could

be increased to a total of 70-80 billion organisms without producing more than a transient local or systemic reaction. The first study included 394 vaccinated children. Of these, 162 were transiently exposed and 29 intimately exposed at some time between four months and four years after vaccination. There were 31 sibling controls for the intimate exposure group. Only 1 vaccinated child developed whooping cough (a mild case), whereas all of the intimate exposure controls developed the disease. In 1937 Sauer⁸ reported a series of cases from the Municipal Whooping Cough Prophylactic Clinic at the Health Center, Evanston, Ill. In a three year period 1,122 children were vaccinated. In this group there were 128 exposures, 94 of them intimate, with only 6 cases of whooping cough developing, a communicability rate of 4.7 per cent.

Probably the largest controlled studies on immunization against pertussis have been those of Kendrick and Eldering in Grand Rapids, Mich. Their vaccine⁹ was prepared from recently isolated cultures in phase I, as described by Leslie and Gardner. The criteria for accepting any particular culture for a lot of vaccine included (1) typical morphology and growth characteristics, (2) agglutination to high titer by antiserum of phase I organisms, (3) ability to produce phase I agglutinins in the rabbit and (4) development of hemorrhagic necrosis on intradermal injection into rabbits. These criteria for the preparation of pertussis vaccine were included in the recommended procedure of the Committee on Standard Methods of the American Public Health Association.¹⁰ Organisms were grown on Bordet-Gengou medium with 15 to 20 per cent human or sheep blood. The organisms were washed from the medium with saline solution, adjusted to a concentration of 10 billion organisms per cubic centimeter, centrifuged, and resuspended in saline solution containing either merthiolate 1:10,000 or 0.5 per cent phenol.

The results of a large study over a period of forty-four months were analyzed by the Committee on Administrative Practice of the American Public Health Association.¹¹ The study included 4,212 children between the ages of 8 months and 5 years. The injected and control groups were of relatively similar size with an equal distribution of age, sex, family size and geographic districts. There was found to be a striking similarity in the incidence of communicable childhood diseases other than pertussis in the two groups. The pertussis attack rate for the vaccinated group was 2.3 per cent and for the control group 15.1 per cent. The communicability rates for known exposures were 12.8 per cent and 68.5 per cent, respectively. When intimate household exposures alone were considered, the communicability rates were 34.9 per cent and 89.4 per cent. Further analysis¹² revealed a secondary familial attack rate of 36.4 per cent in the vaccinated group and of 92.0 per cent in the control group. Thus it would appear that vaccination resulted in about 60 per cent reduction in the risk of being attacked.

The most thoroughgoing unfavorable report on pertussis immunization was that of Doull, Shibley, McClelland and others.¹³ The study was carried out in Cleveland in 1934 and 1935. Their vaccine was prepared from organisms grown for forty-eight hours on Bordet-Gengou medium containing human blood. The organisms were scraped from the medium, washed once with distilled water and resuspended in saline solution containing 0.5 per cent phenol to a concentration of 10 billion organisms per cubic centimeter. The children, who were between the ages of 6 and 15 months, were carefully selected and observed. There were 479 vaccinated children and 496 nonvaccinated children who were older siblings. The attack rates for the period from three months to 112 weeks after immunization were 15.8 per cent and 18.2 per cent, respectively. This indicates that the incidence of the disease in this study was only slightly less for the vaccinated than for the nonvaccinated group.

In a small study of intimate exposure in an orphanage during an epidemic in 1938 Kramer¹⁴ found that, while vaccination two years previously with Sauer's vaccine did not prevent the disease in the 9 test children, it had produced a partial immunity so that the cases were extremely mild. Twelve control children developed moderately severe cases. In the same group 8 children who had previously had whooping cough also developed mild cases. This would appear to indicate that vaccination had been as effective as a previous attack of the disease in conferring immunity. The figures indicate attack rates of 18 per cent and 24 per cent respectively for the vaccinated and nonvaccinated groups and a communicability rate of 100 per cent for both.

Siegel and Goldberger¹⁵ reported the results of an epidemic in a tuberculosis sanatorium. Sauer's vaccine had been given to 101 children whose average age was 2.8 years. A group of 82 control children whose average age was 2.7 years was selected. Attack rates were 8.9 per cent and 13.4 per cent, while communicability rates were 53 per cent and 58 per cent. The cases in the vaccinated group were somewhat milder and of shorter duration than those in the control group. These workers did not feel, therefore, that the vaccine was of notable value. Sauer,¹⁶ on the other hand, reported good results in an epidemic in an orphanage.

These first two studies were small but were controlled and indicated that, while the vaccine did not prevent the disease where there was prolonged intimate exposure as under the conditions in an institution, it did give protection from severe attacks, the resulting cases being mild and similar to those in children with positive histories of the disease.

A controlled study with the Sauer type vaccine was presented by Singer-Brooks.¹⁷ These studies were started in 1925 by Dr. J. J. Miller in the outpatient department of the University of California. Very severe criteria for exposure were held, and prob-

able or possible exposures were excluded. The vaccinated children were over 5 months of age, and sibling controls were used as far as possible. The follow-up study included educational measures and careful laboratory methods to establish bacteriologic diagnoses on primary cases and contacts. For a group of 330 vaccinated children and 200 sibling controls, communicability rates were reported as 7.8 per cent and 97.7 per cent, respectively. The figures indicate attack rates of 1.5 per cent and 22.0 per cent, respectively.

Silverthorne and Frazer¹⁸ reported 2 cases of whooping cough developing among 747 vaccinated children, of whom 91 were exposed. In a group of 161 control children of whom 27 were exposed, 23 cases developed. These figures would indicate communicability rates of 2.2 and 85.1 per cent for the vaccinated and nonvaccinated groups respectively. Vaccination was by means of a dosage of 120 billion organisms in Sauer type vaccine. The children were followed over a period of five years by public health nurses or private physicians.

Miller and Faber¹⁹ reported results on a small controlled series in the Well Baby Clinic of Stanford University, using Sauer type vaccine. Exact criteria of exposure and diagnosis were maintained. Of 346 vaccinated children 11 contracted the disease, indicating a communicability rate of 26.2 per cent. The communicability rate for a group of 182 control children was 88.9 per cent. Statistical analysis shows the difference between the two communicability rates to be significant.

Coppolino²⁰ reported favorable results with the Sauer type of vaccine on a small group of children in Philadelphia. Follow-up studies over a period of four and a half years indicated communicability rates for 152 vaccinated and 160 nonvaccinated children to be 7.1 per cent and 84.9 per cent, respectively. Only intimate exposures of two or more hours were recorded as exposure, and in most cases the exposure was for days or weeks.

Other reports, including those of Garvin,²¹ Mitchell,²² Rambar and his associates,²³ Perkins and his associates,²⁴ Daughtry-Denmark²⁵ and others present comparable results with the most widely used types of vaccine—those of Sauer and of Kendrick. Although these results continue to vary somewhat, the consensus is that solid immunity is conferred on some children and partial immunity on others, such as may occur following an attack of pertussis.

The two types of vaccine used in most of the preceding studies have several differences in their method of preparation. The Sauer type vaccine is an unwashed suspension of organisms, while the organisms used in the preparation of Kendrick's vaccine have been washed once with saline solution. Sauer²⁶ stated that the

supernatant fluid in an unwashed suspension contains an appreciable amount of soluble toxin and that subsequent washing of the original suspension would result in a decrease in the antigenic content of the vaccine. Miller²⁷ found that saline solution and distilled water washings of *H. pertussis* organisms contained a specific substance which would combine with the antibody in antipertussis rabbit serum to give flocculation. It was suggested that this might partly explain the differences in the findings of those using washed and unwashed vaccines. However, Kendrick and Eldering⁹ found that washing the organisms even three times with saline solution did not decrease the typical skin reaction or the ability to produce agglutinins in the rabbit and therefore washed their organisms once with saline solution before making the final suspension. The vaccine of Doull, Shibley and McClelland,¹³ on the other hand, which gave such unfavorable results, was of organisms washed once with distilled water. Miller suggests that perhaps distilled water may denature the surface antigen of *H. pertussis*, while saline solution simply removes a part of it.

Another difference between the vaccines used at present is in the type of blood used in the medium on which the organisms are grown. Sauer vaccine²⁸ is prepared from organisms grown on Bordet-Gengou medium that contains human blood, both for the prevention of sensitization of individuals to animal serum and for the maintenance of the organisms in phase I. The growth at forty-eight hours is scraped into saline solution rather than washed from the medium in order to avoid carrying over any extraneous material. Kendrick and Eldering⁹ on the other hand, used either human or sheep blood and found that both maintained the organisms in phase I. They point out that sheep blood is more uniformly constant and less limited in supply than human blood and have used it in the commercial preparation of their vaccine.

A number of workers have felt that the inclusion of toxic substance in *H. pertussis* vaccine would result in increased potency. In 1930 Mishulow, Mowry and Scott²⁹ prepared a "toxin-vaccine" by growing the organisms on solid medium with a small amount of horse serum-beef heart broth added to encourage elaboration of toxic material. Each lot of vaccine was tested for the presence of toxic substance by the Shwartzman method. This vaccine was found to elicit agglutinins in rabbits to a greater extent than Sauer's vaccine, which was used for comparison. Later Mishulow³ reported results from a small clinical study, using material prepared by a modification of the original method. Agglutination studies showed that a greater response was obtained by the use of the toxin-vaccine than by Sauer vaccine. Shorr,³⁰ Park³¹ and Lapin, Cohen and Weichsel³² reported favorable results of protection in several small studies. It was noted that the local and general reactions to this type of vaccine were greater than with other types. This type of vaccine is distributed by the New York City Department of Health and has been in general use since 1930.

It will be noted that the total dosage of organisms administered in the vaccines in present use ranges from 80 to 120 billion organisms. Madsen⁴ had obtained comparatively favorable results by increasing the dosage to 22 billion from between 50 million and 3.5 billion, as used by the majority of workers at that time. Sauer,³³ feeling that an adequate number of organisms is an important factor, then increased the dosage to 70 to 80 billion. Many feel that 80 billion organisms is sufficient, but Daughtry-Denmark³⁴ and others advocate larger doses to be given to older children and in cases in which complement fixation is not complete after the regular course. Sauer prepared a double strength vaccine of 20 billion organisms per cubic centimeter. This, however, has been largely discontinued, because of the numerous local reactions occurring,³⁵ and now the "intermediate strength" vaccine of 15 billion organisms per cubic centimeter is that in common use.

Recently a number of investigators have attempted to prolong protection through the use of a stimulating dose of vaccine given at intervals after the initial course of immunization, as in the case of immunizations against diphtheria, tetanus, typhoid and other diseases. Wu and Chu³⁶ in 1938 found that a single stimulating dose of 15 billion organisms resulted in a large increase in agglutinative titer above that following the initial vaccination. Lapin³⁷ found close correlation between agglutinative titer, mouse protection and complement fixation in a small study of reinoculated children following exposure to sibling contacts. No cases of the disease developed. Miller,³⁸ Shaw³⁹ and others recommended yearly reinoculation. McLean⁴⁰ suggested a stimulating dose to be given on exposure and on entrance to school. It is now felt that the duration of immunity may perhaps depend in part on subclinical infection following exposures at a time when resistance is high, serving as a stimulus in increasing resistance. Thus the lower incidence of the disease among older children following exposures might be explained.

During the last few years several studies have been made to determine whether alum precipitation of pertussis vaccine might increase its antigenic efficiency as in the case of diphtheria toxoid. Harrison, Franklin and Bell⁴¹ made a small study with a single dose of such a vaccine and obtained a lower incidence among vaccinated children than among controls, although the difference was not statistically significant. Considering the small dosage used, these preliminary results seemed to justify further study. Bell⁴² later conducted a study on the use of two doses of alum precipitated vaccine with a four week interval. The total dosage was 20 billion organisms. This study was very carefully arranged epidemiologically so that the vaccinated and

nonvaccinated groups were identical in all respects without selection, uniformly observed over an adequate period of time and with the definition of clinical pertussis strictly adhered to. Under such well controlled conditions the attack rates were considered significant. For older children the attack rates for vaccinated and nonvaccinated groups were 11.2 per cent and 39.1 per cent, respectively, and for younger children these rates were 9.4 and 29.7 per cent. It was therefore concluded that real protection had been conferred by this vaccine.

Kendrick⁴³ compared her standard vaccine of 70 billion organisms, given over a period of three weeks, with an alum precipitated vaccine, using a total dosage of 30 billion organisms over a five week period in three injections. There was a one week interval between the first and second and a four week interval between the second and third injections. No significant difference was found between the attack rates of the two vaccinated groups. Daughtry-Denmark,²⁵ in a comprehensive study of seven different types of vaccine, found alum precipitated vaccine to be as effective as standard vaccine of the same strength when judged by complement fixation reactions.

The combination of pertussis vaccine with diphtheria and/or tetanus toxoid has been suggested by a number of workers. This would be a convenient means of reducing the number of routine immunization injections generally recommended for infants and children. Bordet⁴⁴ reported the use of mixed *H. pertussis* vaccine and diphtheria toxoid given in three injections at three week intervals. Schütze⁴⁵ and Mathieson⁴⁶ found that, in guinea pigs, alum precipitated pertussis vaccine and diphtheria toxoid inoculated simultaneously were compatible and that the immune response to the toxoid was enhanced, while the response to pertussis vaccine was the same as the response to vaccine alone. Sauer and Tucker³⁵ obtained development of complement fixing antibodies in response to mixed *H. pertussis* vaccine and diphtheria toxoid in three doses at three week intervals equal to that obtained with *H. pertussis* vaccine alone. Daughtry-Denmark²⁵ obtained like results with three doses at one week intervals. Kendrick⁴³ has reported satisfactory response in a small study in which pertussis vaccine alone was injected first, followed in one week by a dose of alum precipitated combined diphtheria toxoid and pertussis vaccine. Lapin,⁴⁷ Daughtry-Denmark²⁵ and Miller and Saito⁴⁸ have reported encouraging results with the combinations of pertussis vaccine, diphtheria toxoid and tetanus toxoid.

Recent investigations in the field of immunochemistry have shown that *H. pertussis* has several distinct antigenic components. A "toxic substance" was described by Bordet and Gengou⁴⁹ in 1909, but it was not until twenty years later that a toxic factor was shown to be

antigenic. Teissier and his associates⁵⁰ and Lawson⁵¹ demonstrated the production of neutralizing antibodies in animals by the use of a toxic filtrate of cell extracts. In 1937 Evans and Maitland⁵² described a thermolabile toxin and were able to produce neutralizing antibodies in animals. Antitoxin production in human beings, however, was not reported until 1940, when Evans⁵³ was able to show that careful injection of the toxin over a long period of time could produce a low antitoxic titer. Flosdorf and Kimball⁵⁴ later demonstrated the thermolabile toxin of Evans and Maitland and described a second less antigenic thermostable toxin. Strean and Grant⁵⁵ prepared what they consider to be pertussis endotoxin by repeatedly freezing and thawing the organisms. The purified preparation was found to contain no agglutinin. They were able to produce an antitoxin in rabbits by inoculation of this material or a toxoid prepared by formaldehyde treatment.

The role of the pertussis toxin in the clinical disease continues to be unknown; but some workers have felt that, if antitoxic as well as antibacterial immunity could be produced by immunization, the individual might have better protection against whooping cough.

Roberts and Ospeck⁵⁶ have prepared a toxic filtrate from broth cultures of strains, not necessarily in phase I, shown to have strong toxic properties. This filtrate is detoxified by solution of formaldehyde and is known commercially as "detoxified pertussis antigen." This preparation has been used in both prophylaxis and treatment. Weichsel and his associates⁵⁷ published a report on a clinical study on immunization in a small group of children. Significant antitoxic titers could be produced if adequate dosage was given. The extent of the immunity produced has been measured by laboratory methods, but clinical data on this study are not yet available. Bullowa and Alterman⁵⁸ and Joslin and Christensen⁵⁹ have described the use of detoxified pertussis antigen as a prophylactic agent, but the studies have not progressed far enough for the results to be properly evaluated. Strean⁶⁰ reports that investigation into the value of combined pertussis bacterial vaccine and pertussis toxoid for prophylaxis is under way.

Several other preparations for immunization to pertussis have been developed and given clinical trials in recent years. These include "Undenatured Bacterial Antigen" and "Topagen." The Undenatured Bacterial

Antigen, known as "U. B. A.," was prepared by Krueger and his co-workers⁶¹ by washing the organisms three times in Locke's solution, grinding them in a ball mill and retaining the filtrate. Dow,⁶² Miller,⁶³ Lawson⁶⁴ and Florsdorf, Kimball and Chambers⁶⁵ have given varying reports on the antigenicity of this substance. Singer-Brooks,⁶⁶ in a small clinical study, found communicability rates for vaccinated and control groups very similar. It has been suggested that a loss of immune principle may in part be due to the fact that the preparation is carried out at room temperature, at which part of the toxin would be destroyed during the procedure. "Topagen" is a soluble antigen which is administered by the intranasal route. It is prepared by macerating the organisms in saline solution, centrifuging, precipitating the soluble antigen by acetone and redissolving in saline solution. Slesinger,⁶⁷ Barksdale⁶⁸ and Gold⁶⁹ reported good results in the treatment of contacts. However, Dow⁶² in animal experiments found Topagen considerably less effective than other vaccines. No large study on prophylaxis with this substance has appeared. It has been suggested for treatment of contact cases.

COMMENT

The data presented here have been assembled from a number of different investigators who have carried out independent studies under a variety of test conditions. Clinical whooping cough is notoriously unpredictable in the severity of individual attack and epidemic course. However, the majority of the studies have indicated that the incidence of whooping cough can be lowered by the administration of either the Sauer or the Kendrick type of pertussis vaccine in adequate dosage, after six months of age. These new vaccines appear to lower the attack rate in vaccinated individuals and to decrease the severity of the disease.

Although extensive laboratory studies have been carried out in an effort to determine the degree of immunity conferred by pertussis vaccines, the relationship between serologic findings and actual protection of the individual is not clear. There has been in the past no simple index of immunity, such as a reliable skin test. Within the last few years new skin testing techniques have been reported,⁷⁰ with promising preliminary results. If the results of these methods continue to be satisfactory the control of whooping cough will be greatly simplified.

At present the incidence and severity of the disease as the result of actual exposure under adequately controlled field conditions are the only means of proving the efficiency of whooping cough vaccines. Improved culture methods⁷¹ have given more accurate bacteriologic diagnoses and have aided somewhat in differentiating whooping cough caused by *H. pertussis* from a similar but milder paroxysmal disease caused by *Bacillus parapertussis*.⁷² Wider use of these methods is advocated for the more adequate control of whooping cough.

The role of pertussis toxin in the disease has not been established. A lack of correlation has been found between the production of antitoxic antibodies and the severity of an attack. The antitoxin is demonstrable for only a short time after the disease and is not found in normal serums. Experimental evidence, on the other hand, has shown agglutinins to phase I organisms over a long period of time after either an attack of the disease or vaccination against it.⁷³ It would seem, therefore, that whole bacterial vaccines would produce the proper protective antibodies.

A report of the Committee on Therapeutic Procedures for Acute Infectious Diseases and on Biologicals of the American Academy of Pediatrics⁷⁴ recommends immunization against pertussis as a routine procedure with the following specifications: 1. Pertussis Vaccine Immunizing (Sauer) 6 cc. of vaccine standardized to 15 billion organisms per cubic centimeter, three injections at three week intervals, or (on the West Coast) 2.5 cc. of vaccine standardized to 40 billion organisms per cubic centimeter, three injections at two to four week intervals. Pertussis Vaccine Immunizing (Kendrick and Eldering) 7 cc. of vaccine standardized to 10 billion organisms per cubic centimeter, four injections. The committee recommends the use of phase I vaccine. 2. Pertussis detoxified antigen, 1.5 to 2.0 cc. subcutaneously for three to five doses every two to three days. 3. Alum precipitated pertussis vaccine (Harrison-Bell) 0.2, 0.3 and 0.5 cc. every four to eight weeks, standardized at 40 billion killed pertussis organisms per cubic centimeter.

Vaccines for the prophylaxis of whooping cough were eliminated from New and Nonofficial Remedies in 1931 because of the fact that convincing evidence of their value was not presented during the years in which they were in extensive use. There was no general agreement on the method of preparation and administration, and clinical reports from physicians varied widely. However, the evidence presented in this report from studies during the period since 1931, with more recent preparations, demonstrate that whole bacterial vaccines prepared from virulent phase I *H. pertussis* given in proper dosage after 6 months of age do confer significant protection as measured by reduction in the attack rate and severity of pertussis.

THE MALE CLIMACTERIC

Some fifteen years have elapsed since the first report on the use of standardized estrogenic substance as treatment of women in the climacteric syndrome. Skepticism about the nature of the menopause and the value of its endocrine therapy has been allayed and the indications for use have been more clearly defined. Those clinicians who believed that the symptoms of the climacteric were wholly psychogenic in etiology and to be treated by sedation or psychotherapy are now convinced of the dependability and efficacy of a variety of estrogenic materials, natural and synthetic. Conviction has been aided by widespread clinical success. Objective proof has included the demonstrations of the effect on the vaginal epithelium and the mammary tissues of the two ovarian hormones both estrogenic and progestational in type. Apparently only the estrogens are involved in the prevention or relief of the autonomic and psychic symptoms which are usually spoken of as the menopause syndrome. A further important observation has been the demonstration of an increase in the urinary excretion of gonadotropic material following castration or the occurrence of the spontaneous menopause. This phenomenon is apparently uniformly observed unless the pituitary is in some way destroyed or removed. The phenomenon has therefore been interpreted as meaning an excessive secretion of pituitary gonadotropic hormone following the elimination or atrophy of the ovaries. There is still room for debate as to whether this is excessive secretion by the pituitary or the excretion by the kidneys of unused anterior lobe gonadotropic hormone.

More recently extensive debate among clinicians has concerned the validity of the concept of the male climacteric syndrome. Castration of male adults is apt to be followed by a group of symptoms essentially identical with those noted in women after removal of the ovaries or spontaneous menopause. Men who do not suffer surgical extirpation of the testicles may never experience such symptoms. Not infrequently, however, complaints of a similar character are made by men in

any age from the third decade on. Whether this is to be attributed to testicular atrophy or failure of testicular secretion is the point in question. Many cases of such disorders have been treated with synthetic testosterone propionate or methyltestosterone, the latter being demonstrably active when administered orally. Satisfactory clinical improvement has been reported by several clinicians. Such success might possibly be attributed to the general stimulation of secondary sex characters by these substances or even to the increase in muscle tissue as well as in physical vigor produced thereby. However, the recent work of Heller and his associates from the Wayne University Medical School shows that there is an increase in the anterior pituitary gonadotropic hormone in the urine of men who have been castrated, of men whose testicles have atrophied and of a group of patients who fit the concept of a male climacteric. This is analogous to the situation in the female. Therapy with androgenic materials has given distinct relief to these patients, fitting likewise the probability of the existence of the climacteric. Another group of individuals with somewhat similar complaints had rather indifferent benefits from the use of the androgen; they were shown also to be different in that there was no significant increase of the pituitary gonadotropic hormone in the urine samples investigated.

The facts that are here cited serve to indicate with increasing probability that the male climacteric is just as truly a syndrome based on endocrine disturbances as is the menopause syndrome in women. Unfortunately objective means for making these differentiations are still limited to investigative clinics and hospitals.

PHYSIOLOGIC ACTION OF IN VIVO ANTICOAGULANTS

Such substances as heparin and dicumarol and to a lesser degree salicylates are known to have definite anticoagulant properties in vivo. The mechanism of this action, as yet not clearly defined, has been partially clarified by the work of numerous investigators; this information has been recently summarized by Quick.¹ In the case of heparin the strongly acid property of the structure assigned to it (mucotin-sulfuric acid-like) by Charles and Todd is considered to be significant. By virtue of this property it is able to form stable salts with many proteins, particularly those with basic reaction. The union of heparin and an as yet unidentified protein co-factor of the albumin fraction of the blood is advanced by Quick to explain the antithrombic activity of heparin. The complex so formed has the power to bind thrombin, thus preventing this substance from assuming its essential role in the coagulation of blood. The participation of this co-factor appears to be necessary, since heparin by itself is not an anticoagu-

1. Quick, A. J.: The Anticoagulants Effective in Vivo with Special Reference to Heparin and Dicumarol, *Physiol. Rev.* 24:277 (July) 1944.

lant. This reaction is reversible when a strongly basic protein like protamine is added to the blood. The antithrombic activity is lost when the heparin breaks its combination with the albumin factor in favor of the more strongly basic protamine, thus releasing the thrombin. Brinkhous and his associates² describe another *in vivo* action of heparin. This involves the blocking of the conversion of prothrombin to thrombin. Here again an unidentified plasma factor appears to be necessary. At present it is not clear whether this represents an interference at the thromboplastic or prothrombic level. Ferguson and Glazko³ reason that the effect occurs at both points. If this was so the presence of heparin would offer a block to coagulation at several stages.

The effect of heparin on blood platelets is important, since the starting point of a thrombus is a small mass of agglutinated platelets. There does not appear to be a direct action of heparin on the platelets, but clumping of these cells is prevented as a result of the anticoagulant property. Baronofsky and Quick⁴ did not find clumping or reduction in the number of platelets in blood to which 0.25 mg. of heparin per cubic centimeter had been added, while Best and his co-workers did not prevent agglutination of platelets in dog blood with the clotting time raised to six hours by heparin. Greater doses were effective in preventing the clumping, however. In general a lack of uniformity in degree of response to heparin has been evident. Possible explanations lie in the variability of the compound itself as obtained from different sources and aberrations in the plasma protein of the subjects studied.

From studies on the hemorrhagic disease in cattle resulting from ingestion of spoiled sweet clover hay has come the isolation by Link and his associates⁵ of the active principle, dicumarol. Its chemical structure has been determined and mode of action postulated. The anticoagulant effect is attributed to a depression of synthesis of prothrombin rather than a direct effect on this substance. Quick has demonstrated that prothrombin consists of two components. One of these is known to be diminished in dicumarol poisoning. The mechanism of this reduction is not clear, but it has been suggested that there results an inability of the liver to utilize vitamin K for the production of this prothrombin component, possibly because of a toxic effect on the enzyme system producing prothrombin. The fall in prothrombin after administration of dicumarol takes place rather slowly, reaching its lowest point in about forty-eight to ninety-six hours and returning to

normal in a week. Bollman and Preston⁶ found a fall of about 15 per cent after three days when a dosage of 10 mg. per kilogram was administered to dogs. According to Quick a critical minimum dose appears necessary, and greatly increased amounts will not hasten the fall in prothrombin. The return of the prothrombin level to normal may be speeded by administration of natural vitamin K₁ oxide. Using this material, Davidson and MacDonald⁷ reported a reversal of dicumarol effect in 4 out of 5 cases by the use of large doses. There is thought to be either a neutralization of the toxin or a synthesis of prothrombin in the presence of excess vitamin K. Synthetic vitamin K counteracts the dicumarol hypoprothrombinemia in most cases when large doses are used. The transfusion of either fresh or citrated banked blood has not been consistently effective in restoring the prothrombin. Thus there is not available at present any thoroughly dependable agent to combat the hypothrombinemia induced by dicumarol.

The antiprothrombic activity of dicumarol in the liver appears to be its sole effect on this organ. The livers of animals subjected to repeated injections of this material have been found entirely normal at necropsy by several investigators. Liver function tests likewise show no impairment. When dicumarol is used in the presence of existing hepatic damage or when fever exists, a heightened response is reported. There is conflicting evidence of the effect on capillary fragility and sedimentation rate. Wright and Prandone state that increase in capillary fragility was not detected in the patients receiving dicumarol under their observation. However, dicumarol has been noted to cause vascular dilatation and purpura after massive doses. As found with the use of heparin, when the blood coagulation time is greatly delayed by administration of dicumarol, platelet clumping no longer occurs.

More recently Link and his associates and independently Rapoport and his co-workers have made the observation that salicylates administered either orally or intravenously cause hypoprothrombinemia which can be prevented or counteracted by administration of synthetic vitamin K. Several workers who have studied this effect of the salicylates believe that the action is essentially that of dicumarol but less powerful. One of these substances may actually complement the activity of the other. Salicylates show an effect in cirrhosis similar to the increased response found with dicumarol. The potentialities of these actions are great whether or not the agents are used therapeutically under adequate control or exert their effect as an undesirable side reaction. More information on methods of controlling the effects of these anticoagulants and on their potential toxicity is urgently needed.

CORONARY HYPERSUSCEPTIBILITY

Klinge¹ and Vaubel² of pre-Nazi Germany showed fifteen years ago that in rabbits parenteral administration of large doses of horse serum is often followed by vascular and perivascular alterations in the smaller branches of the coronary arteries, other parts of the vascular system being unaffected. They described the coronary lesions as closely resembling those of "human rheumatism." Interest attaches to these observations, owing to the increasing use of large doses of antiserum in clinical medicine and to the contemplated use of heterologous plasma or plasma fractions in human transfusion. The experiments were therefore repeated by Rich and Gregory³ of Johns Hopkins University and later studied in greater detail by Fox and Jones⁴ of St. Louis University.

The St. Louis investigators made careful microscopic studies of 31 adult albino rabbits previously given one or more intraperitoneal or subcutaneous injections with large doses (10 cc. per kilogram) of horse serum followed by one or more 1 cc. doses given intravenously. The rabbits were killed at arbitrary intervals after the last injection. The investigators found severe coronary lesions in 20 of the 31 injected rabbits, with 7 rabbits showing milder coronary alterations. All noninjected controls were negative.

The vascular changes noted in the injected animals were characterized by intimal hyperplasia and proliferation of adventitial cells, the latter being frequently interspersed with lymphocytes and mononuclear cells or surrounded by them, with an occasional polymorphonuclear neutrophil. Fibroid degeneration was occasionally noted in the intima and media, but without definite necrosis. The coronary lesions closely resembled those often described under such terms as "rheumatoid arteritis" or "rheumatic carditis."³ The vascular changes were usually limited exclusively to the coronary arterioles, though mild vascular lesions were occasionally found in the liver, lungs, testes, kidneys or mesentery.

Fox did not find any significant relationship between the severity of the coronary lesions and the number of doses, time interval or sequence of large and small doses of horse serum. Some rabbits exhibited severe vascular changes following a single large dose of serum. There was, however, a suggested correlation between the severity of the coronary lesions and the degree of acquired cutaneous sensitivity to horse proteins. All animals with the necrotic type of reaction to routine skin tests exhibited material degenerative changes in the coronary arterioles. Equally manifest changes, how-

ever, were occasionally noted in rabbits with non-necrotic skin sensitivity. Twelve of the 31 rabbits developed Fleisher's⁵ "serum sickness reaction" of the ears, following a large parenteral dose of horse serum. This "scarlatinal reaction" was invariably associated with appreciable degenerative changes in the coronary arterioles.

Aside from its bearing on current problems of serum therapy and plasma transfusion, this latest confirmation of the Klinge-Vaubel phenomenon is of basic clinical interest. It is experimental proof that the coronary arterioles are more highly susceptible to mild toxic injury than other parts of the vascular system.

RENAL DAMAGE FROM SULFONAMIDE COMPOUNDS

Shortly after the sulfonamide compounds came into general use, physicians recognized that the kidney may be damaged in the course of therapy with these drugs. Two types of renal complications were observed: (1) those due to mechanical obstruction of the pelvis, the ureters and the renal tubules by crystals of the sulfonamide compounds and (2) those due to toxic lesions of the kidney without obstruction. Combination of the two forms has likewise been described. In addition to tubular necrosis, which is the usual expression of damage by toxic substances, instances were observed in which interstitial tissue reaction with necrosis was also present. Murphy and his associates¹ observed 1 such instance in the series reported by them. They feel that this type of reaction is probably an expression of severe idiosyncrasy on the part of the renal tissue to the drug. This inflammatory response was also seen in tissues outside of the kidney represented by giant cells and perivascular granuloma-like cell accumulations suggesting a similarity with periarteritis nodosa and similar lesions. The hepatic damage observed in these cases is probably related to the nephrotoxic complications.

Study of the clinical data of 14 patients with renal insufficiency following use of sulfonamide compounds in relation to postmortem observations on 13 revealed that the quantity of the sulfonamide compound administered and the drug level in the blood appeared to be unimportant in producing the renal damage. As much as 41 grams and as little as 0.6 gram was responsible for fatal renal injury. In a few of their cases deposits of crystals of the drugs in the urinary tract causing some degree of mechanical obstruction were found associated with the nephrotoxic lesion; this was not the

rule, however, as in most of the cases the nephrotoxic lesions were independent of mechanical blocking. Microscopic alterations in tubular epithelium were observed all the way from simple degeneration to tubular necrosis and intense inflammatory reaction outside the nephron. The investigators feel that these tubular lesions represent degrees in the severity of one process rather than different kinds of response. The study failed to correlate the clinical features with the specific site for the renal tubular damage.

Of the numerous toxic complications caused by sulfonamide compounds, that affecting the kidney is most serious. Fortunately these complications are comparatively uncommon. The mechanical type of complication, particularly that outside the kidney, in the pelvis and the ureter, responds best to therapeutic measures. When, however, obstruction occurs within the kidney a cure is not easily accomplished, although always retrograde lavage should be done and the drug discontinued. Precipitation of the sulfonamide compound is the etiologic factor in these obstructions. Precipitation should be prevented as far as possible by the administration of adequate fluids and maintenance of an alkaline urine.

Current Comment

PLASMA LEVELS OF VITAMIN A AND CAROTENE IN RHEUMATIC SUBJECTS

The explanation for the greater frequency of rheumatic fever in persons in low income groups has been sought in a number of studies. Shank and his colleagues¹ recently determined the levels of vitamin A and carotene in the plasma on four groups of subjects whose intakes of vitamin A had been calculated. The first included 12 normal children in the high income class; their average daily intake was 109 per cent above the recommended amount for age and sex. The other three groups consisted of children with rheumatic infection who no longer showed signs of the active disease but whose diets contained varying quantities of vitamin A. Those in the second group were 24 children who received more than average amounts of vitamin A, their diets averaging 23 per cent above the calculated requirements. In the third group were 46 children who received vitamin A in adequate amounts with an average intake only 5 per cent in excess of calculated needs. The fourth group included 25 children with low vitamin intakes, the average for the group being 44 per cent less than optimum. The subsequent observations revealed a clearcut association between the levels of vitamin A and carotene in the plasma as related to the intake of vitamin A in the

diets. Regardless of the concentration of vitamin A or carotene in the plasma prior to the onset of active exacerbations of the disease, there is a fall in the level of vitamin A in the plasma with the development of acute rheumatic fever; the carotene in the plasma was not significantly altered quantitatively during rheumatic attacks. Furthermore, it was found that the degree of decrease of vitamin A in plasma varies directly with the intensity of the rheumatic attack. In the presence of severe attacks, concentrations in the plasma varied between 0 and 70 international units of vitamin A per hundred cubic centimeters of plasma. Delayed or decreased absorption of vitamin A was thus shown in patients with rheumatic fever. Nevertheless, uncertainty prevails as to whether vitamin A is destroyed in some abnormal manner or whether it is utilized normally but with increased speed of metabolism and that this accounts for its lowering in the presence of the active disease. Whether or not the vitamin A disturbance is a causative factor in the rheumatic process or merely a result of the process remains for further investigation.

DISHWASHING IN RESTAURANTS

The sanitary procedures of restaurant operation, including the adequacy of the methods of sanitizing eating and drinking utensils, are matters of general concern. Recently mobile laboratory units of the United States Public Health Service have cooperated with state and local health departments in making swab tests of restaurant utensils in numerous communities in different sections of the country. Unpublished reports of this work, according to Andrews,¹ reveal that improvement is needed in dishwashing methods in most, if not all, of the communities visited. This disappointing condition exists in spite of the availability of adequate information on choice of detergents and machine and hand washing technics. The fault is primarily in personnel. Frequently a person doing the dishwashing has not been properly instructed in technic. Good equipment is worthless if improperly operated. Since the outbreak of the war, the problem of maintaining good sanitation in restaurants has obviously become intensified by shortages of manpower, materials, increased customer loads and reduction of health department inspection facilities. In the face of evidence that the amount of disease spread in restaurants is increasing, health departments should intensify their efforts at control. Experience has shown that health authorities achieve the most satisfactory results by education rather than by policing. Properly organized training courses for employees of restaurants will probably prove more effective than any other one measure. As pointed out by Andrews, restaurant sanitation is an important public health activity, and wartime conditions with the probability of long continued overloading of restaurants in many areas gives this problem a special urgency.

MEDICINE AND THE WAR

ARMY

NEW VACCINE TO PROTECT ARMY AGAINST SPREAD OF INFLUENZA

The War Department announced recently plans for the procurement and possible use of a vaccine to combat the spread of influenza in the Army, should the disease occur in epidemic form. The plans are based on evidence presented by the Commission on Influenza under the Army Epidemiological Board. The vaccine will not be administered routinely but will be given only on definite indication of the threat of influenza and only to personnel under risk of exposure to the disease. A statement of policy and a summary of the evidence for the prophylactic value of influenza vaccine was recently issued to all medical officers in a technical bulletin from the Office of the Surgeon General.

One of the main projects of the Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, ever since its establishment in 1941, has been the development of protection against influenza. This board, now called the Army Epidemiological Board, is under the presidency of Dr. Francis G. Blake, Dean of Yale University School of Medicine, New Haven, Conn. Under this board the Commission on Influenza, of which Dr. Thomas Francis Jr., professor of epidemiology at the University of Michigan School of Public Health, is director, was asked in 1943 to carry out a controlled clinical trial of the prophylactic efficacy against epidemic influenza of a concentrated vaccine containing the killed influenza viruses types A and B. In cooperation with a number of civilian and military agencies an extensive investigation was carried out. On the whole, the results showed that there was a reduction of about 75 per cent in the incidence of influenza among the vaccinated as compared with the unvaccinated controls and that loss of manpower hours was reduced because the illness in vaccinated persons was milder and shorter. The vaccine which was used was developed by Dr. Thomas Francis Jr., Dr. Jonas E. Salk and their associates.

BRIG. GEN. CHARLES R. GLENN APPOINTED DEPUTY AIR SURGEON

Brig. Gen. Charles R. Glenn, surgeon at the AAF Training Command, Fort Worth 2, Texas, has been appointed Deputy Air Surgeon. Col. Neely C. Mashburn, General Glenn's executive since July 1943, will succeed him. In his new assignment General Glenn will serve as assistant to Major Gen. David N. W. Grant, Surgeon on the Air Staff at AAF headquarters in Washington, D. C. Both General Glenn and Colonel Mashburn are Regular Army officers.

General Glenn, who graduated from Jefferson Medical College of Philadelphia in 1914, became a first lieutenant in the reserve on May 13, 1917. He was commissioned in the Regular Army before the end of the first world war. It was largely under his direction that training command surgeons, together with a group of highly specialized psychologists, developed the now famous system for the selection and classification of air crew trainees—pilots, bombardiers, navigators and gunners—a system designed to find the right man for the right job. In June and July of this year General Glenn made a sixty day world encircling inspection and observation flight during which he covered 40,000 miles, visiting U. S. combat air forces in every active theater except England and Alaska.

Colonel Mashburn graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1914. He went overseas and served with the medical corps in Paris in February 1918 at the 18th Hospital of Evacuation and Operations south of Dunkirk, with the 32d, 29th and 88th divisions of the Alsace front in the x-ray section of a field hospital, with the Johns Hopkins unit in a general hospital center near General

Pershing's headquarters and finally at La Rochelle, just above Bordeaux. After his return to the United States in July 1919 he was ordered to the station hospital for the 1st Division at Louisville, Ky. From May 1920 to 1934 Colonel Mashburn experienced a variety of duty tours. He served as an instructor in the School of Aviation Medicine, Randolph Field, Texas, from 1934 to 1940. In 1941 he was appointed command surgeon for the Southeast Training Center at Maxwell Field. He became post surgeon at Ellington Field, Texas, in the Central Flying Training Command, known then as the Gulf Coast Training Center.

NEW PENICILLIN STUDY INSTITUTED AT FORT BRAGG

Dr. Charles Rammelkamp, member of the commission on Acute Respiratory Diseases, Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General, and Capt. William Leifer, M. C., Regional Hospital, Fort Bragg, North Carolina, recently spent several days in the Office of the Surgeon General conferring on the new method of administering penicillin developed by Capt. Monroe J. Romansky, M. C., at the Army Medical Center. The new technic prolongs the action of penicillin by suspending it in a mixture of 4 per cent beeswax and peanut oil. Dr. Rammelkamp will act in a consulting capacity with Dr. Leifer, who is instituting a study of the method at Fort Bragg Regional Hospital. It is believed that the new method will have important effects on the use of this agent.

COL. ROBERT H. KENNEDY APPOINTED TO MAYO GENERAL HOSPITAL

Col. Robert H. Kennedy, former director of surgery at Beckman Hospital, New York, and attending surgeon at the New York Post-Graduate Hospital, has recently been appointed chief of surgical service at Mayo General Hospital, Galesburg, Ill. Dr. Kennedy, a veteran of World War I, succeeds Col. Emory Neff, former surgical chief, who left for treatment at Percy Jones General Hospital. Dr. Kennedy was called to active duty in World War II with the rank of lieutenant colonel in June 1942. He was promoted to colonel on April 3, 1943. Dr. Kennedy graduated from Columbia University College of Physicians and Surgeons in 1912.

DR. H. JACKSON DAVIS WITH ARMY CIVIL PUBLIC HEALTH DIVISION

Dr. H. Jackson Davis, chief medical officer of the State Department of Social Welfare, Albany, N. Y., has been granted military leave from the department to accept a commission as major in the newly established Civil Public Health Division, U. S. Army Medical Corps. The Civil Public Health Division will develop public health policies and practices in liberated and occupied countries in all war theaters, establish supervisory and liaison relations with local public health officials and provide certain essential medical supplies in those areas. Dr. Davis is a veteran of World War I. He graduated from Yale University School of Medicine, New Haven, Conn., in 1926.

MAJOR ALFRED GOLDEN GIVEN NEW ASSIGNMENT

Major Alfred Golden, formerly of Madison, Wis., who has been on duty for the past four years at the Army Medical Museum, has been transferred to the Division of Health and Sanitation, Office of the Coordinator of Inter-American Affairs. Dr. Golden will be assigned to duty in Latin America to study the pathology of certain tropical diseases.

TROOPS EXPOSED TO FILARIASIS PARASITE BEING OBSERVED AT WAKEMAN GENERAL HOSPITAL

More than five hundred servicemen who have been exposed to filariasis are being observed at the Wakeman General Hospital, Camp Atterbury, Indiana. Although the presence of the disease has been established in only a small percentage, the condition of none of the men is serious. The men were returned to the United States in accordance with War Department policy of evacuating military personnel from endemic regions after exposure to the disease in order to avoid complications that might develop following prolonged exposure. All the men just returned were evacuated after a comparatively short exposure to filariasis, and there is little likelihood that the more serious permanent consequences, including elephantiasis, will develop.

Transmission of the disease is possible only when immature forms of the parasite are circulating in the blood of an infected person. Such larval forms must be taken up by a mosquito in order to complete their development. None of these immature forms have been found in the blood of any of the returned soldiers. Consequently there is no risk that they will spread the disease in this country. Most of the men will receive furloughs, after which they will return to the convalescent hospital. It is expected that the majority will return to duty within a short time.

THIRTY-TWO MEDICAL OFFICERS RECEIVE REGULAR ARMY APPOINTMENT

Thirty-two medical officers who successfully completed examinations for regular army appointment held in January were nominated in the Senate recently and confirmed by that body as first lieutenants in the Regular Army Medical Corps. The officers who hold grades higher than those to which they are appointed in the Regular Army will retain such higher temporary grades. Those nominated were:

Capt. A. L. Baker Jr., Dover, N. J.	Capt. J. M. McIver, Boston.
Major B. H. Bennett, Washington, D. C.	1st Lieut. G. B. Milburn, San Antonio, Texas.
Capt. A. S. Blauw, Boulder, Colo.	Capt. T. M. Mulford, San Diego, Calif.
Major H. Boyd Jr., Kingston, N. Y.	Capt. J. R. Paul, Lincoln, Neb.
Capt. D. H. Calhoun, Roswell, N. M.	Lieut. Col. G. S. Richardson, Roswell, N. M.
Capt. J. S. Clapp, Erie, Pa.	Major H. L. Riva, Charleroi, Pa.
Capt. W. D. Dugan, Eugene, Ore.	Capt. J. N. Schaeffer, Miamisburg, Ohio.
Capt. H. V. Ellingson, Rochester, N. Y.	Capt. Edward Shaw, West Hartford, Conn.
Capt. R. C. Feamster, New Orleans.	Major F. R. Sloan, Marquette, Ia.
Capt. C. H. Flood, Ramsey, N. J.	1st Lieut. N. R. Spencer (M. Res.), Bethesda, Md.
Major E. J. Genetti, Bessemer, Mich.	1st Lieut. R. W. Thometz (M. Res.), Oak Park, Ill.
1st Lieut. F. E. Harrigan Jr. (M. Res.), West Hartford, Conn.	Capt. C. F. Vorder Bruegge, Memphis, Tenn.
Capt. K. D. Heuser, Denver.	Lieut. Col. J. E. Walther, Rushville, Ind.
Capt. R. R. Jones, Dallas, Texas.	
Major V. C. Kelly, Baltimore.	
Capt. K. A. Koerner, St. Louis.	
Capt. Robert Landesman, New York.	
Capt. R. E. Lau, York, Pa.	
1st Lieut. J. P. McEvoy (M. Res.), St. Paul.	

RECONDITIONING NEWS LETTER

A new publication, *Reconditioning News Letter*, is now being distributed monthly by the Office of the Surgeon General to all ASF hospital commanders and service command surgeons. Its aim is to familiarize hospital personnel with new ideas, practices and procedures connected with the reconditioning program. Sources of the items published are reports made by inspecting officers from the Surgeon General's Office, chiefs of the reconditioning branches in service commands, medical officers and others familiar with the program.

INCIDENCE OF POLIOMYELITIS AMONG U. S. TROOPS

In the two week period ended September 2, 20 cases of poliomyelitis were reported by army installations in the United States. This represents a slightly higher incidence than for the corresponding period last year. The total incidence since the first of the year is somewhat lower than in the corresponding eight month period of 1943. While most of the cases have occurred in the states which have a high civilian incidence of the disease, they have been widely scattered.

ADVANCE IN AURAL REHABILITATION PROGRAM

Borden General Hospital, Chickasha, Okla., has installed electroacoustical apparatus enabling it to fit the individual patient with the best combination of manufactured hearing aids. Such equipment is rarely found in civilian institutions and represents a progressive step in the aural rehabilitation program. Hoff General Hospital, Santa Barbara, Calif., and Deshon General Hospital, Butler, Pa., will be similarly equipped in the near future.

ARMY AWARDS AND COMMENDATIONS

Captain Cecil D. Conrad

The Soldier's Medal was recently awarded to Capt. Cecil D. Conrad, formerly of Highland Park, Mich. The citation accompanying the award reads "On March 22, 1944, when a fully loaded bomber crashed on takeoff at Decimennanu, Sardinia, he observed that one engine was cutting out as the airplane sped along the runway and realized that a crash was imminent. He started his vehicle and arrived at the scene of the accident immediately after the plane struck. The terrific impact, which shattered and set fire to the B-26, killed one member of the crew and seriously injured others. With complete disregard for his own safety, and despite exploding ammunition and the great danger of fire setting off the bombs, he made his way into the wreckage and, with the aid of a comrade, removed the stricken crew members from the danger area. His heroism and selfless devotion to duty in risking his life to save others reflect highest credit on himself and the armed forces of the United States." Dr. Conrad graduated from Wayne University College of Medicine, Detroit, in 1941 and entered the service Oct. 24, 1941.

Major John Connell

Major John Connell, formerly of Des Moines, Iowa, has been awarded the Silver Star Medal "for gallantry in action in October 1943 in Italy. During an attack by an infantry regiment over a river Captain Connell followed the infantry across the river and by his own ingenuity organized routes of evacuation of battle casualties. All through the attack, which lasted two days, Captain Connell supervised the proper function of new routes and constantly reconnoitered to improve, shorten or hasten the evacuation even though the routes were under enemy fire. He made several trips across the river, which was still under enemy observation and heavy artillery and mortar fire. Undoubtedly the ingenuity and perseverance of Captain Connell, and the calm and courageous manner in which he performed his duties, saved the lives of many battle casualties and was instrumental in their being evacuated more quickly from the front lines. His coolness under fire and devotion to duty were exemplary and a credit to the armed forces of the United States." Dr. Connell graduated from Washington University School of Medicine, St. Louis, in 1937 and entered the service Feb. 10, 1941.

Captain Harlan Alfred Alexander

Capt. Harlan A. Alexander, formerly of Minneapolis, was recently presented with the Bronze Star Medal "for heroic achievement" in military operations against the Japanese on Attu Island in May 1943. The citation read "Capt. Harlan A. Alexander, Medical Corps, United States Army. For heroic achievement in connection with military operations against the enemy on May 16, 1943 during the Attu operation. After a furious battle an infantry company was forced to withdraw under withering enemy fire, leaving 5 casualties which had not yet been evacuated. After the withdrawal Captain Alexander, with complete disregard for his own safety, three times led a small group of aid men up a mountain and successfully evacuated 5 wounded men, although the entire route was over enemy terrain. His courageous action was an inspiration to the men of the battalion and resulted in saving the lives of 3 of the 5 wounded soldiers. His courage, coolness under fire and disregard for his personal safety reflect great credit on himself and the military service." Dr. Alexander graduated from the University of Minnesota Medical School, Minneapolis, in 1930 and entered the service Sept. 8, 1942.

NAVY

FIRST AID STATION AT GUAM

Seven machine guns set up in the windows of a besieged American first aid station held a bitterly contested sector of the Marine front lines for several hours recently at Guam. The station was commanded by Lieut. George W. Eldering, formerly of Los Angeles, who in desperation had asked for weapons support when the Japs ignored the aid station's immunity under international law and had launched an attack toward it. The station was located in a shell battered Jap storehouse well in advance of the Marine lines and had been established by Dr. Eldering and his men while some of the fighting of this campaign raged about them. "It was the best place we could find at the time," Dr. Eldering stated. "The front and side walls of the storehouse were still standing and offered some protection, though the roof and back wall were gone. After I had ordered the guns set up, I could find only five 'fit Marines to man them, so 2 of the patients took over the others. I ordered all patients evacuated immediately after first aid because I wasn't sure we could hold out for any length of time in that spot. Finally the orders came for us to fall back to a position about 500 yards behind the front lines. It was then we learned that our machine guns had held that part of the front alone."

NAVY AWARDS AND COMMENDATIONS

Lieutenant Commander Tom T. Flaherty

The Air Medal was recently awarded to Lieut. Comdr. Tom T. Flaherty, formerly of Long Beach, Calif. The citation accompanying the award read "For meritorious achievement in aerial flight as crew member of an R4D Transport Plane attached to the South Pacific Air Transport Command from July 15 to 25, 1943. When his craft was unable to land on the densely overgrown jungle terrain while transporting urgently

needed supplies to our forces on New Georgia Island, Lieutenant Commander Flaherty skilfully performed his duties and rendered invaluable assistance to his pilot in accurately dropping the cargo as the unarmed plane flew in at terrific speed and at tree top level to avoid intense enemy antiaircraft fire and aerial opposition, making several hazardous runs on the targets to complete the mission and frequently returning to base without the protection of covering planes. Lieutenant Commander Flaherty's cool courage and unwavering devotion to duty under extremely difficult conditions contributed materially to the success of these vital missions and were in keeping with the highest traditions of the United States Naval Service." Dr. Flaherty graduated from the University of Southern California School of Medicine, Los Angeles, in 1939 and entered the service July 14 of that year.

Lieutenant Commander Ben H. Keyserling

The Silver Star Medal was recently awarded to Lieut. Comdr. Ben H. Keyserling, formerly of Columbia, S. C. The citation accompanying the award read:

"While his unit was engaged with the enemy, Commander Keyserling displayed a high degree of courage, initiative and professional skill under the most hazardous of conditions.

"Dr. Keyserling, after all available stretchers had been evacuated to the rear with wounded, advanced to within a few yards of the front line assault companies, coolly and expertly treated wounded as they fell and evacuated them to the rear under heavy machine gun and rifle fire, for a full half hour.

"The fact that many were saved who would otherwise have perished may be attributed to Dr. Keyserling's courage . . . in the rendering of treatment. His actions were a great inspiration to all those with whom he came in contact and were in keeping with the highest traditions of the Navy."

Dr. Keyserling graduated from the Medical College of the State of South Carolina, Charleston, in 1940 and entered the service Aug. 28, 1941.

MISCELLANEOUS

TYPHUS COMMISSION MEDAL
AWARDED TO FOUR

The United States of America Typhus Commission Medal has been awarded by order of the President to Dr. Abdel Wahed El Wakil, Egyptian minister of health, and to three British brigadiers of the Royal Army Medical Corps for the help they have given representatives of the commission in investigating typhus in the Middle East and southern Italy. The members of the Royal Army Medical Corps are Brigadiers John S. K. Boyd, George B. Parkinson and Rudolf W. Galloway.

Dr. Wakil's citation reads:

"For meritorious services in connection with the work of the United States of America Typhus Commission. Ever since the arrival of the United States of America Typhus Commission group at Cairo, His Excellency, Dr. Wakil, as Minister of Health, has cooperated closely with the Commission. Through his interest and influence, facilities and opportunities were made available for the investigation of typhus fever in the laboratory and hospital, while extensive tests and new developments in methods for the control of typhus fever were made possible. The information derived from the results of these studies, conducted with the cooperation of Dr. Wakil, has been of benefit to the military forces."

The following is Brigadier Boyd's citation:

"For exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. From the time of the arrival of the first contingent of the United States of America Typhus Commission at Cairo in January 1943 and throughout the remainder of that year, Brigadier Boyd assisted the commission in formulating and effectuating programs for research on typhus fever and in development of measures for control. He furnished detailed information concerning the incidence of typhus fever in British forces in the Middle

East in a manner which advanced coordination between American and British procedures for typhus control. Brigadier Boyd cooperated with the United States of America Typhus Commission in clinical studies, conducted to evaluate the properties of antityphus serum. In his capacity as a member of the Middle East Supply Center (Medical Section), Brigadier Boyd was extremely helpful and cooperative in arranging for distribution of typhus vaccine throughout the Middle East. Through his generous cooperation and through his many years of experience in the field of pathology, Brigadier Boyd as a consultant aided the Commission in practically every phase of its work in the Middle East."

Brigadier Parkinson's citation reads:

"For exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. During the epidemic of typhus in Naples, in the period of Dec. 20, 1943 to Feb. 20, 1944 Brigadier Parkinson actively cooperated with the United States of America Typhus Commission and rendered service of the greatest value in support of the typhus control program in southern Italy. Through his assistance to the Commission measures which prevented the spread of typhus in southern Italy were greatly strengthened."

Brigadier Galloway's citation follows:

"For exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. During the period of from Dec. 20, 1943 to Feb. 20, 1944, the critical period of the outbreak of typhus at Naples and in southern Italy, Brigadier Galloway actively supported the work of the United States of America Typhus Commission in southern Italy. In addition, he took special steps to see that the danger of typhus fever was brought to the attention of all British medical officers in the area. He initiated an active typhus control program throughout the entire military forces in southern Italy."

MALARIA EPIDEMIC DANGER IN U. S. IS REMOTE

Major O. R. McCoy, chief of the Tropical Disease Control Division in the Preventive Medicine Service of the Office of the Surgeon General of the Army, recently stated that he believed there is little danger of any serious epidemic of malaria in the continental United States traceable to soldiers returned from malarious battle fronts. It was reported recently that among soldiers the malaria situation has improved to a point where the effectiveness of combat units is no longer seriously threatened so long as "atabrine discipline" is properly maintained. Nevertheless some civilian authorities have indicated their fear that the return of malaria victims to the homeland might cause new epidemics or reestablish the disease endemically in areas which have not known it for several generations. Major McCoy stated that such fears are unwarranted. He pointed out that there is no reason to presume that mosquito control work, on which our principal dependence has been placed for malaria control, will not continue to operate effectively despite the presence of returned soldier victims. Brig. Gen. Hugh J. Morgan, head of the Medicine Division, who is chief consultant in medicine to Major Gen. Norman T. Kirk, Surgeon General of the Army, pointed out that the research work and experiences of the Army, Navy and other governmental agencies in malaria during this war have shed much light on many phases of the disease. "We are able to assure the American public that there is no reason for unfounded fears of malaria, if the disease is properly treated," he said.

Every soldier in a malarious area receives "suppressive treatment"—a small dose of atabrine six days a week, which controls the disease if he should contract it while in the lines and keeps him functioning as part of his unit. If the disease should develop, or if it appears after he is withdrawn to a nonmalarious rest area, he is given substantially larger curative doses, repeated each time the disease reappears. Most victims of vivax malaria have one relapse. At the same time the soldier is trained to protect himself against the mosquito which transmits the infection. He is supplied with mosquito netting, with mosquito repellents and "mosquito bombs" to clear out his tents or living quarters, and he is taught not to expose himself at sunrise or sunset.

HEALTH NEWS FROM EUROPE

Public health work in Naples, after the initial cleanup and refitting of hospitals, was largely a matter of modernizing and supplementing the efforts of the Italian civilian government. Drug supplies and equipment were imported and modern developments in technics applied. Rapid treatment centers for victims of venereal disease were instituted and hospitals established for prostitutes. Wider case finding was stimulated and steps in education were undertaken.

Special emphasis also was laid on malaria control measures, on sanitation to prevent typhoid and dysentery infections and on antityphus work. Owing to overcrowding and lack of water and soap, an epidemic of lice borne typhus was building up when the Allies moved into Naples.

Typhus is a seasonal disease, and the number of cases usually begins to increase in the fall and winter and reaches its peak in April and May. It is particularly virulent among the underfed and poorly housed parts of the population, and during and after the last war it literally killed millions in eastern Europe. In Naples public health measures taken under the direction of the allied military government and the Typhus Commission of the United States stopped the epidemic cold for the first time in history. In January nearly 1,000 cases were reported, in February there were fewer than 200 cases, and in March case incidence was unimportant.

A few sporadic cases still occur in Naples, but the strenuous delousing campaign, use of repellent powders perfected for the U. S. Army and the immunization with U. S. Army vaccine of civilian public health workers proved effective. Exact figures on the death toll of the epidemic have not yet been assembled, but the rates ran about as usual, from 4 per cent among children to 54 per cent among persons over 70 years old. There were no cases among Allied soldiers. Naples had not had a reported case of typhus for fifteen years prior to this outbreak.

Records of the local régime were so confused that it was possible to form no clear picture of previous health averages for Naples, but current conditions in the city are described by the Army as good. Typical of the Fascist records was an instance applying to a Sicilian city in which certain buildings were listed as hospitals with so many beds allotted for civilian care. Some of the buildings so listed were actually houses of prostitution.

LIEUT. OLIVER AUSTIN MISSING IN ACTION

Dr. Jean Austin, wife of Lieut. Oliver Austin, who has been missing in action since July 5, will carry on her husband's work. He vanished after taking off on a mercy flight July 5 from Churchill, Canada. His destination was Eskimo Point, 160 miles north, where he hoped to check an epidemic among the Eskimos and forestall danger of its spreading to the United States Army Air Force station near Churchill, where he was post surgeon. Searching parties found the plane wrecked on July 9 on a submerged reef in the Hudson Bay. The pilot's body was found but no trace of Lieutenant Austin. Dr. Jean Austin, who is resident surgeon at Cook County Hospital, Chicago, plans to leave for the isolated Hudson Bay outpost, 1,000 miles north of Winnipeg, where there are no other doctors for a distance of 600 miles, as soon as possible. Drs. Jean and Oliver Austin both graduated from Northwestern University Medical School, Chicago, in 1943 and 1941, respectively. Dr. Oliver Austin entered the service in September 1943.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, September 23, page 242)

CALIFORNIA

Stanford University Hospitals, San Francisco. Capacity, 372; admissions, 9,588. Dr. Anthony J. J. Rourke, Superintendent (residents—surgery, obstetrics and gynecology, anesthesia, psychiatry, medicine, October 1).

ILLINOIS

Walther Memorial Hospital, Chicago. Capacity, 209; admissions, 5,665. Mr. William C. Martens Jr., Superintendent (3 interns).

MICHIGAN

Saginaw General Hospital, Saginaw. Capacity, 151; admissions, 3,961. Mrs. Kate J. Hand, Superintendent (intern).

MISSOURI

Christian Hospital, St. Louis. Capacity, 135; admissions, 3,201. Miss Agnes Heman, R.N., Superintendent (2 interns, 1 resident, mixed service).

NEW YORK

Beth David Hospital, New York City. Capacity, 187; admissions, 3,985. Mr. Harold M. Salkind, Executive Director (6 interns, October 1). Ellis Hospital, Schenectady. Capacity, 470; admissions, 14,385. Miss Mary G. McPherson, R.N., Administrator (interns, resident, mixed service, October 1).

TENNESSEE

Protestant Hospital, Nashville. Capacity, 222; admissions, 4,895. Mrs. Elizabeth S. Hain, R.N., Superintendent (3 residents—mixed service).

WASHINGTON

Pierce County Hospital, Tacoma. Capacity, 239; admissions, 2,768. Dr. Burton A. Brown, Administrator (intern, October 1).

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Mayo General Hospital, Galesburg, Ill.: Blood Dyscrasias, Drs. Louis R. Limarzi and Howard L. Alt, October 4.

Camp Ellis, Camp Ellis, Illinois: Orthopedic Problems of General Interest, Drs. Edward L. Compere and Paul B. Magnuson, October 4.

Chanute Field, Rantoul, Ill.: Gallbladder and Liver Disease, Drs. Andrew C. Ivy and Walter L. Palmer, October 4.

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

Sept. 25, 1944.

Sensenich Urges Physical Fitness Program

A nationwide program of physical fitness, "not a Hitler youth movement, but routines of living for the purpose of hardening or attainment of physical vigor," was advocated by Dr. R. L. Sensenich of the Board of Trustees of the American Medical Association in his testimony before the Pepper committee. He was the first witness called at the opening of the past week's three day session, when the health condition of four to five million young American men found physically and mental unfit for the armed forces was under discussion.

"The greatest significance in reports of rejections for the armed forces," said Dr. Sensenich, "would seem to be in the notable lack of self interest and effort to secure or maintain a high level of mental and physical fitness. Those without recognizable defects fail to observe even the simplest program of regulation or discipline directed to the maintenance of good health. Routines of living for purposes of hardening or attainment of physical vigor are often referred to only with contempt."

Dr. Sensenich revealed that plans are well along for the broadest national activity to stimulate an interest in physical fitness. These are directed to homes, schools, churches, labor and industry and social and professional groups. This activity is being organized under leadership of a joint committee for the American Medical Association and the Committee on Physical Fitness of the Federal Security Agency. The work will be financed from many private groups. Dr. Sensenich estimated that approximately one out of six men were rejected because of remediable defects. Failure was most often due to lack of interest or willingness to accept treatment to correct conditions rather than to inability to obtain such medical service. He said that there are numerous provisions for those unable to pay for medical service. Final failure to obtain needed medical care, if it is sought, he said, generally rests on failure of some agency of government to carry out the purpose for which it is directed to assist those in need. On the question of availability of medical care, he said that the Procurement and Assignment Service for Physicians, Dentists and Veterinarians had done an excellent job in preventing serious depletion of medical personnel where their services were needed by the civilian population.

Cutting Hospital and Medical Costs for Wage Earners

Dr. C. Rufus Rorem, director of the Hospital Service Plan Commission of the American Hospital Association, told the Pepper committee that if the government provided all necessary medical and hospital care for the indigent, doctors and hospitals could reduce their rates so much that all wage earners, even with very low incomes, could probably provide such care for themselves and their families. Dr. Rorem said that providing hospital and medical service for beneficiaries of public assistance, who at most make up no more than 15 per cent of the population, may seem a trivial procedure that avoids the basic need of adequate care for all the people, but he declared that it "strikes directly at the heart of an important economic problem of sickness. If the hospitals and physicians were individually (and as groups) relieved of financial responsibility for care of the indigent public," he said, "the subscription rates and hospital payments of the Blue Cross plans might be reduced to make participation possible by even the low income employed person and his dependents."

During the past week's hearing, views of labor leaders were expressed. The American Federation of Labor went on record as believing that the remedy to the national health problem lies in the principle of social insurance to apply to the health needs of all the people. Its spokesmen were in favor of the programs for hospitals and district hospital centers proposed by Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service.

In addition to the American Medical Association spokesmen, testimony was given by Professor Walter W. Palmer, chair-

man, Committee on Postwar Medical Service, American College of Physicians; Dr. Jean Curran, dean, Long Island College of Medicine and member of the board, Bingham Associates Fund; Dr. Samuel Proger, medical director, Pratt Diagnostic Hospital, Boston; Dr. Victor Heiser, chief medical consultant, National Association of Manufacturers; Dr. Leverett D. Bristol, chairman, Health Advisory Council, U. S. Chamber of Commerce; Dr. John P. Peters, secretary, Committee of Physicians for Improvement of Medical Care; Dr. George Stevenson, medical director, National Committee for Mental Hygiene; Dr. E. I. Robinson, president, National Medical Association; Dr. Ernst P. Boas, chairman, Physicians Forum; Dr. John Radford Boling, president, Florida State Medical Society; Dr. Perry Prather, general practitioner, Hagerstown, Md., and Dr. T. Henshaw Kelley, secretary, California Physicians Service.

Commission on Children Urged by Pepper Committee

Three recommendations from the Pepper Subcommittee on Wartime Health and Education, made at the conclusion of sittings here this past week when the juvenile delinquency problem was discussed, were (1) Establishment of a commission for children and young people in the Office of War Mobilization, (2) fuller participation of children in the home front war effort through a central administrative authority and (3) national publicity and educational policy to acquaint the people of the United States fully with facts about children and their needs.

Juvenile delinquency, the hearings indicated, does not have any single cause, and it cannot be cured by any single remedy. Prevention is believed to be the soundest approach to the problem, the committee found from testimony of witnesses with experience in child health and welfare. Many governmental agencies are struggling with the problem, but overall leadership and coordination are needed. It was pointed out in a summary of testimony that, although there are at least twelve agencies in the federal government alone performing special services for children, the services of none of them, from the Children's Bureau to the Federal Bureau of Investigation, can be spared. Nor is there any federal agency known to the committee which is set up in a way to provide adequate leadership and coordination in delinquency prevention.

Veterans Hospital Facilities Extended

Addition of 14,100 beds to the hospital system of the Veterans Administration has been given presidential approval, reports Brig. Gen. Frank T. Hines, chairman of the Federal Board of Hospitalization. This includes approximately 2,700 beds for mental patients, 7,900 for general medical and surgical care and 3,500 for tuberculous patients. This program is in addition to projects already approved for 17,400 beds in mental hospitals, 2,100 for general medical and surgical patients and 500 for the tuberculous. It is reported that most of the 20,000 beds are already under construction. Altogether, 34,100 beds are to be added to present Veterans Administration hospitals.

The latest program was approved after a nationwide study of prospective needs for veterans' hospitals, made jointly by the Veterans Administration and the Federal Board of Hospitalization. The study does not recommend individual sites for new hospitals or suggest where additions should be made. The way is cleared now for detailed planning by the Veterans Administration.

General Hines said that planning for future hospitalization of veterans must be continued. Locations will be chosen and hospitals designed two or three years in advance, the presidential approval having ordered that the whole program be reviewed frequently.

It is estimated that there will eventually be about 112,700 hospital beds available for veterans' care, and of the 27,700 to be made available for 1947 some 5,700 are for Veterans Administration patients in other federal, state and private hospitals. Adding some 12,800 beds that will be available for domiciliary care, a grand total of about 125,500 beds will be available ultimately to veterans.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

Society News.—Dr. Joseph Jordan Eller, New York, will address the Waterbury Medical Society, November 9, on "Tumors of the Skin."

Yale Library Acquires Herb Cabinet.—The Yale Medical Library recently acquired the herb cabinet of Dr. Seth Bird (1733-1805), Bethlehem. The *Connecticut State Medical Journal* reported that no Connecticut physician of his time was more famous as a practitioner or medical preceptor than Dr. Bird. On June 14, 1941 the Beaumont Medical Club of Connecticut paid tribute to Dr. Bird in a visit to his house, which at that time was owned by Mr. William B. Sprague of New York City. On this occasion Dr. Creighton Barker, New Haven, presented a paper on Dr. Bird.

DISTRICT OF COLUMBIA

Personal.—Dr. Hugh H. Hussey Jr. has been named chairman of a medical advisory committee appointed by the district office of price administration to pass on all applications for extra food rations for convalescents and persons in ill health. Other members of the committee are Drs. Roy L. Sexton, Roger O'Donnell Jr., Thomas F. Collins Jr. and James M. Moser. —Dr. Nelson Mercer, medical officer at Virginia Polytechnic Institute, Blacksburg, Va., has been named chief medical officer of the tuberculosis division of the Gallinger Municipal Hospital, effective August 1. Dr. Mercer succeeds Dr. Charles P. Cake, who resigned to enter the U. S. Public Health Service. —Dr. Herbert P. Ramsey has been appointed chairman of the health division of the Council of Social Agencies.

Blood Bank Incorporated.—The new community blood plasma bank, successor to the former Office of Civilian Defense blood bank, has been incorporated and will soon begin operation, according to *Medical Annals* (THE JOURNAL, June 24, p. 587). Dr. Roger M. Choisser is the new president of the bank, and members of the governing board include Dr. John A. Reed vice president, Dr. Charles Stanley White, Dr. Oscar B. Hunter, Dr. John M. Orem and Fred A. Walker of the Central Labor Union secretary-treasurer. Plans are to maintain bank supplies with contributions by patients after they recover or by their friends. It will be a nonprofit organization, and plasma will be available at the cost of production plus a donation of blood.

ILLINOIS

Personal.—Dr. Joseph S. Maxwell, formerly missionary to Ethiopia, has been appointed physician at Wheaton College, it is reported.

Chicago

The Bevan Lecture.—Dr. Howard C. Naffziger, professor of surgery, University of California Medical School, San Francisco, will deliver the sixteenth annual Arthur Dean Bevan Lecture before the Chicago Surgical Society, October 6. The subject of his lecture will be "Exophthalmos and the Thyroid: Experiences with Major Surgery of the Orbit."

Mr. Shepard Joins Saunders Company as Art Editor.—Mr. Willard C. Shepard, for many years connected with Rush Medical College and recently Rush associate in illustration studios at the University of Illinois College of Medicine, has been appointed art editor of W. B. Saunders Company, publishers, Philadelphia and London, in which position he will be available for consultation with authors in the preparation of illustrations for important textbooks. Mr. Shepard studied under the late Professor Max Brödel of Johns Hopkins University School of Medicine, Baltimore. Since 1916 he has been medical artist to Rush Medical College and the Presbyterian Hospital and for the past several years a general faculty member of the department of illustration of the University of Illinois College of Medicine. In his new work Mr. Shepard will concentrate on the more effective utilization of medical illustration to the benefit of medical education and clinical practice.

INDIANA

Personal.—Dr. Love E. Pennington, superintendent of the Milledgeville, Ga., State Hospital, has been appointed to a similar position at the Madison State Hospital, North Madison.

Medical School Affiliates with St. Elizabeth Hospital.—An affiliation of St. Elizabeth Hospital, La Fayette, with the Indiana University School of Medicine, Indianapolis, for postgraduate instruction of the hospital's interns and staff has been announced by Dr. Willis D. Gatch, dean of the medical school. The affiliation, which was requested by Sister M. Amelia, superintendent, and Sister M. Renata, librarian, of the La Fayette hospital is the first of a series of joint arrangements by which the university's school of medicine will extend its facilities to local hospitals. The university will outline the training, send members of the faculty to conduct monthly meetings of interns and staff, and conduct examinations. The major portion of the instruction will be conducted by La Fayette physicians under Dr. Franklin S. Crockett, director of postgraduate instruction of St. Elizabeth Hospital.

LOUISIANA

New Diagnostic Center.—The New Orleans Diagnostic Center has been opened in the old criminal courts building for the examination of women arrested for violations of the moral code. Women found to be infected with venereal diseases will be sent to the Delgado Memorial Hospital, a unit of Charity Hospital, New Orleans.

Anton Carlson to Give New Lecture.—Dr. Anton J. Carlson, professor emeritus of physiology, University of Chicago School of Medicine, will deliver the first lecture to be given at the Tulane University of Louisiana School of Medicine, New Orleans, October 2, under the newly created Alpha Omega Alpha Lectureship. Established by the Tulane University Stars and Bars chapter of Alpha Omega Alpha, one lecture will be given each academic year on the initiation of new members. Twelve Tulane students will be initiated on October 2 in addition to Dr. Hiram W. Kostmayer, dean of the medical school, who has been chosen an honorary member.

Symposium on the Heart and Circulation.—The Louisiana State University School of Medicine, New Orleans, will conduct a symposium on the heart and circulation, October 25-27. There will be no fee. Those interested are invited to attend. Among the speakers will be Drs. Maurice B. Visscher, University of Minnesota Medical School, Minneapolis, who will discuss cardiac efficiency and metabolism; Isaac Starr, University of Pennsylvania School of Medicine, Philadelphia, the ballistocardiograph, and Frank N. Wilson, University of Michigan Medical School, Ann Arbor, electrocardiography. Other speakers will be from Tulane University of Louisiana School of Medicine and Louisiana State University.

MASSACHUSETTS

Nutrition Instruction.—The Harvard School of Public Health through its department of nutrition is expanding its teaching activities in nutrition. Nutrition A, consisting of three lectures per week for the first semester (November through February) covers the following subjects: proteins; fats; carbohydrates; minerals; vitamins; water; foods as sources of nutrients; nutritional requirements versus recommended allowances; losses of food nutrients in processing and the enrichment and fortification of foods; food habits; nutrition in relation to pregnancy, lactation, childhood, adolescence, dental health, medicine and blood regeneration; the use and abuse of commercial vitamins and mineral preparations; food fads versus facts; food budgeting; evaluation of nutritional status—dietary histories, laboratory methods, clinical studies, surveys; evaluation of diets; mass feeding; nutrition in industry; the nutritionist in a public health program; tools for nutrition education; nutritional problems of rehabilitation; nutrition in preventive medicine and public health. Nutrition B is offered throughout the entire year and consists of practical experience under supervision in food clinics in a community nutrition project or in experimental nutrition, depending on the student's qualifications and interests. Nutrition C, a weekly journal club and seminar in nutrition covering both fundamental and applied nutrition, meets throughout the academic year.

NEBRASKA

The C. W. M. Poynter Foundation.—Alumni and friends of Dr. Charles W. M. Poynter, dean of the University of Nebraska College of Medicine, Omaha, have set up an endowment fund to establish the C. W. M. Poynter Foundation. The purpose of the foundation will be to create a Poynter lectureship and fellowship at the college of medicine and the

painting of a portrait of Dr. Poynter. Persons wishing to contribute to the fund should address Dr. Willson B. Moody, treasurer of the foundation, 530 Medical Arts Building, Omaha 2.

NEW JERSEY

Brandenburg Arrested for Illegal Narcotic Sale.—Dr. Leopold W. A. Brandenburg, 57 years old, Union City physician who in recent years has been involved in several criminal complaints (*THE JOURNAL*, July 11, 1942, p. 893 and Sept. 12, 1942, p. 135), was arrested by federal narcotic agents, September 12, on a charge of illegally selling narcotics. He was held in \$5,000 bail to await action by the federal grand jury. Assistant United States Attorney Charles Stanziale said the charges involved the sale of morphine to "four or five drug addicts over a period of time." The arrest was made by federal narcotic agents at the physician's office at 2802 Hudson Boulevard, Union City.

Court Orders Physician Restored to Civilian Job.—The U. S. Circuit Court of Appeals for the Third District, Philadelphia, in its first decision construing terms of the amendment to the Selective Service Act which requires employers to reinstate returned veterans to their jobs, ruled on September 12 that a medical director for an industrial corporation is an employee within the meaning of the law and entitled to his old job after discharge from the armed forces, according to the *New York Times*. The unanimous decision, written by Judge William H. Kirkpatrick, orders the General Cable Corporation at Perth Amboy, N. J., to reinstate Dr. Albert E. Kay, Perth Amboy, as the company's medical director. Dr. Kay enlisted in December 1942, after he was classified 1-A by his draft board, and attained the rank of captain in the army before he was discharged for physical disability. The company refused to rehire him, claiming that he was an independent contractor rather than an employee. It also contended that, since an employees' health association for which Dr. Kay had been medical examiner had engaged another physician and refused to take Dr. Kay back, it would be more beneficial to the employees if the same doctor was medical director for both the company and the association. Judge Kirkpatrick ruled that the law does not say a returned veteran must be an employee but is intended to protect "a position in the employ of an employer" and that Dr. Kay held such a position. As to the company's contention that there would be "loss of efficiency" and "additional expense" if separate doctors were employed by the company and the employees' association, Judge Kirkpatrick said that if such a claim was upheld it "would defeat the main purpose of the act and limit its operation to merely capricious or arbitrary refusals." The ruling was made on an appeal taken by Dr. Kay from a decision handed down by Judge Thomas F. Meaney of the New Jersey Federal District Court last February 7 dismissing a lawsuit the doctor had filed to compel the company to reinstate him.

NEW YORK

Cancer Teaching Day.—On October 17 a cancer teaching day will be held at the Hermann M. Biggs Memorial Hospital, Ithaca, under the auspices of the Medical Society of the County of Tompkins, the state medical society and the division of cancer control of the state department of health. The speakers will be Drs. John H. Garlock, New York, and John J. Morton Jr., Rochester, on "Carcinoma of the Colon" and "Bone Tumors" respectively. An evening session will be addressed by Drs. Andrew H. Dowdy, Rochester, on "Epithelioma of the Skin" and Frank E. Adair, New York, "Carcinoma of the Breast."

Graduate Lectures.—On October 31 Dr. Frank L. Meleney, New York, will discuss "Penicillin Therapy" before the Nassau County Medical Society in Rockville Centre. Dr. Foster Kennedy, New York, discussed "The Neuroses: Related to the Manic-Depressive Constitution" before the Otsego County Medical Society, September 13, and Dr. Stockton Kimball, Buffalo, addressed the St. Lawrence and Jefferson county medical societies, September 14, on "The Diagnosis and Treatment of Malaria and the Dysenteries." These lectures are jointly sponsored by the state medical society and the state department of health.

New York City

Gastroenterology Conferences.—Bellevue Hospital announces a series of conferences on gastroenterology beginning October 2 and continuing every Monday throughout the coming year. The sessions will consist mainly in the presentation of a clinical, pathologic and radiologic study of current abdominal cases that have come to operation or necropsy.

Meeting on Diabetes.—The New York Diabetes Association was addressed September 28 at the Blumenthal Auditorium, Mount Sinai Hospital, New York, by Drs. Martin G. Goldner and George Gomori, both assistant professors of medicine at the University of Chicago School of Medicine, on "Alloxan Diabetes" and "Histology of the Normal and Diseased Pancreas" respectively.

Columbia Receives Penicillin.—A grant of 100,000 Oxford units of penicillin was recently made to students of the College of Pharmacy at Columbia University for demonstration purposes, newspapers reported August 30. The drug is not suitable for human consumption, it was stated, but will prove an important addition to the laboratory to enable pharmacy students to gain first hand knowledge of the drug.

Million Dollar Fund for Crippled Children.—The Association for the Aid of Crippled Children, 580 Fifth Avenue, will receive about 10 million dollars under the will of Mrs. Annie Kirk Belding, who died September 4. The late Mrs. Belding's husband, Milo M. Belding, who died in 1931, had provided that the income from a trust fund after the death of his wife was to go to the association. The gift will be known as the Milo M. Belding Fund.

Health Education.—The Health Education Committee of the National Publicity Council for Health and Welfare Services, Inc., announces two health education clinics at the Hotel New Yorker, New York, October 2. One on printed matter, to be addressed by Milton Glover, Arthur Kudner Advertising Agency, and Horace H. Hughes, director of public information, Maternity Center Association, will be a practical analysis of printed pieces and posters in the health field. The second, on radio, will be a clinical discussion of the various types of radio programs; speakers will be Paul F. Lazarsfeld, director, Office of Radio Research, Columbia University; Harrison B. Summers, manager, public service division, Blue Network, and Herta Herzog, radio research department, McCann Erickson Advertising Agency.

Mayor Vetoes Boric Acid Bill.—Mayor Fiorello H. La Guardia recently vetoed the Vogel bill passed by the city council, which would require that all boric acid products be labeled "poison," according to the *Journal of the Medical Society of the County of New York*. The mayor based his veto on three main points:

1. He doubted that the jurisdiction or police powers of the city council covered the subject.
2. He regarded the question as one of a highly technical and medical nature, more properly and wisely entrusted to the board of health.
3. He preferred opinions of several medical authorities, including Dr. Ernest L. Stebbins, city health commissioner, and Dr. Edward S. Godfrey Jr., state health commissioner.

It was stated that Mayor La Guardia found that the amendment to the sanitary code, recently passed by the city board of health and effective September 15, adequately meets all the precautions. The amendment governs the handling for purposes of selling of boric acid in the form of powder, crystals or solutions unless the container contains a label with the words "boric acid" and "Caution—Not for Internal Use Except as a Mouth Wash, Eye Wash or Douche."

PENNSYLVANIA

Philadelphia

Personal.—Gustav J. Martin, Sc.D., has been appointed research director of the National Drug Company; he has been assistant director in charge of the division of chemistry for the Warner Institute for Therapeutic Research, New York.

Joint Medical Meetings.—On September 13 the Philadelphia County Medical Society and the College of Physicians of Philadelphia opened their regular joint medical meetings with a talk, among others, by Dr. Reginald H. Smithwick, Boston, on "Experiences with the Surgical Treatment of Hypertension." Subsequent speakers will include:

- John F. Enders, Ph.D., Boston, Immunity in Mumps (John Herr Musser Lecture), October 4.
- Dr. Andrew C. Ivy, Chicago, The Gastrointestinal Hormones, Their Physiology and Application, November 8.
- Dr. Stanley P. Remann, The Cancer Problem as It Stands Today (Thomas Dent Mutter Lecture), December 6.
- Dr. George W. Thorn, Boston, Asthenia of Adrenal and Thyroid Origin—Differential Diagnosis and Treatment, January 10.
- Dr. Chester S. Keefer, Boston, Penicillin (Nathan Lewis Haskell Lecture), February 7.
- Dr. Joe V. Meigs, Boston, The Delay Period in the Diagnosis of Cancer, March 14.
- Dr. Charles C. Wolfarth, The Diagnosis of Coronary Artery Disease (Mary Scott Newbold Lecture), April 4.

SOUTH CAROLINA

Personal.—Dr. Henry W. Tobias, for more than six years chief medical officer of the Veterans Administration Facility, Columbia, has resigned. Newspapers report that he will return to Washington to live.—Dr. Caleb W. Harris, Bishopville, recently completed fifty years in the practice of medicine.

Executive Director Named for Ten Point Program.—Mr. M. L. Meadors, Florence, a practicing attorney, has been elected executive director of the "ten point program" sponsored by the South Carolina Medical Association (*THE JOURNAL*, June 17, p. 505). The program was launched September 1 and is intended to raise the level of medical care for all people of South Carolina and keep the practice of medicine in the hands of the medical profession. The plan was approved at the recent annual meeting of the state medical association. Mr. Meadors formerly served as a member of the South Carolina House of Representatives.

Refresher Courses.—The Medical College of the State of South Carolina, Charleston, will conduct its third annual refresher course November 1-3 with the following speakers: Drs. Hilger Perry Jenkins, Chicago; Albert David Kaiser, Rochester, N. Y.; Eugene M. Landis, Boston; Bret Ratner, New York; Harold George Wolff, New York; George Edward Pfahler, Philadelphia; Paul Titus, Pittsburgh; Henry N. Harkins, Baltimore, and Julius Lane Wilson, New Orleans. Dr. Victor Johnson, Secretary of the Council on Medical Education and Hospitals, American Medical Association, Chicago, will address the banquet session on founders day, November 2, on "Medicine After the War." A special session on physical medicine will be held Friday in the Stark General Hospital Medical Library. The speakers will include Lieut. Col. Charles H. Fair, M. C., Major John G. Reid, M. C., Capt. Arthur M. Puce, M. C., on "Physical Medicine and War Injuries" and Lieut. Elizabeth Kelly, P. T. A., and Captain Puce on "Peripheral Nerve Injury: The Role of Splinting and Physical Therapy in Preoperative and Post-operative Care," a demonstration. A refresher course organized by the South Carolina Society of Ophthalmology and Otolaryngology will be conducted October 31 to November 2, among others, by Drs. Henry M. Goodyear, Cincinnati; James S. Shipman, Philadelphia; James W. White, New York, and Oscar V. Batson, Philadelphia.

. TEXAS

Memorial to Dr. Randall.—The amphitheater in the outpatient clinic building of the University of Texas Medical Branch, Galveston, has been named Randall Hall in honor of the late Dr. Edward Randall, professor emeritus of therapeutics, formerly chairman of the board of regents of the University of Texas and chairman of the board of directors of the Sealy and Smith Foundation. Dr. Randall died August 12.

Changes in the Faculty at Baylor.—The following appointments to the clinical faculty of the Baylor University College of Medicine, Houston, have been announced:

- Dr. Theodore R. Hannon to associate professor, clinical surgery.
- Dr. Frank O. McGhee to associate professor of orthopedic surgery.
- Drs. John E. Skogland and Zidella M. S. Brenner to associate professors, clinical neuropsychiatry.
- Dr. Paul R. Stalnaker, associate professor, clinical urology.
- Dr. A. Louis Dippel, Salt City City, to associate professor, obstetrics.

WEST VIRGINIA

Advisory Committee Named for Physical Restoration Program.—A professional advisory committee to the physical restoration section of the West Virginia board of vocational education has been appointed by the West Virginia State Medical Association at the request of F. Ray Power, director of the new division "because of their outstanding contribution in a similar advisory capacity to the adult physical restoration program of the department of public assistance." Members of the committee are Drs. Thomas H. Blake, St. Albans, and Hugh A. Bailey and Thomas G. Reed, Charleston. The physical restoration program of the division of vocational rehabilitation includes provisions for surgical, medical and psychiatric care, hospitalization, physical therapy, occupational therapy and artificial appliances for clients who meet the criteria for eligibility for the services of the division and who are medically indigent. The duties and responsibilities of the professional advisory committee will include meeting from time to time to advise the division of rehabilitation and the supervisor of physical restoration with respect to general policies, setting of standards, selection of rates and methods of payment for services, supplies and prosthetic appliances, methods of medical

reporting and record keeping by case workers, and assisting in interpreting to the professional personnel and institutions participating in the program the policies and procedures adopted by the state board of vocational education. Dr. Norman G. Angstadt, Fayetteville, director of the bureau of county health work of the state department of health, has been named as part time medical (administrative) consultant. His work will include day to day consultation with the supervisor of physical restoration in individual cases and specific medical problems, advice with regard to the execution of the policies for physical restoration, assistance to the supervisor in representing the state agency in its contacts with the medical and associated professions, assistance in the maintenance of the standards established by the state agency for the selection of physicians, hospitals and other medical personnel and facilities qualified to serve various types of cases and for payment to physicians, hospitals and others, and assistance in training the rehabilitation case work staff. The physical restoration program is already functioning with medically indigent clients being provided with such prosthetic appliances, surgical correction and therapeutic treatment as is necessary to restore them to physical fitness for jobs in industry, which is the objective of all physical restoration in the new division.

GENERAL

National Hearing Week.—The week beginning October 22 has been designated National Hearing Week and will be devoted to the theme "Twenty-Five Years of National Service in the Cause of Better Hearing." The observance will be emphasized at the twenty-fifth anniversary meeting of the American Society for the Hard of Hearing at the Waldorf-Astoria Hotel, New York, November 10-12. This will be the eighteenth annual observance of National Hearing Week.

Graduate Courses.—The American College of Physicians has announced its autumn postgraduate courses, the first on cardiology, to be held at the Massachusetts General Hospital, Boston, October 2-7. Other courses include:

General Medicine, University of Oregon Medical School, Portland, October 9-14.

Internal Medicine, Center for Continuation Study, University of Minnesota Medical School, Minneapolis, October 9-14.

Allergy, Roosevelt Hospital, New York, October 16-21.

Special Phases of Internal Medicine, various Chicago institutions, October 23-November 4.

Special Medicine, various Philadelphia institutions, December 4-15.

Dr. Hanson Joins Red Cross.—Dr. Millard C. Hanson, who recently resigned as city health director of Richmond, Va., has been appointed medical director for the American Red Cross in charge of the Pacific area, with headquarters in San Francisco. Dr. Hanson will have charge of medical activities of the Red Cross in seven Western states and the territory of Alaska. Dr. Hanson, who graduated at Rush Medical College, Chicago, in 1923, served in the Richmond position for more than eight years.

New Journal of Clinical Psychology.—A new *Journal of Clinical Psychology* will make its debut in January 1945 under the auspices of the University of Vermont College of Medicine, Burlington. Dr. Frederick C. Calkins, Burlington, Vt., is the editor. The new publication seeks to improve interprofessional relations between psychology and psychiatry. It will appear quarterly and will be limited to the publication of original research reports and of authoritative theoretical articles in the field of clinical psychology. The journal hopes to bring about closer understanding between psychology and the medical profession particularly in the borderline fields of psychometrics, guidance, counseling, child development and remedial work with speech, reading and special disabilities.

Special Society Elections.—Dr. Walter A. Younge, St. Louis, was chosen president-elect of the National Medical Association at its annual meeting in St. Louis, August 17, and Dr. Emery I. Robinson, Los Angeles, was installed as president. Other officers are Dr. John T. Givens, Norfolk, Va., general secretary, and Dr. Eugene T. Taylor, St. Louis, treasurer. The 1945 session is planned for Louisville, Ky.—Will Ross, a director of the Wisconsin Anti-Tuberculosis Association, Milwaukee, was recently chosen president-elect of the National Tuberculosis Association at its meeting in Chicago. Mr. Ross is the first layman to be elected to this office in thirty-two years and the second in the association's history.

Cancer Society Changes Name.—The American Society for the Control of Cancer, Inc., has changed its name to the American Cancer Society, Inc. In the future the society's lay organization, the Women's Field Army, will be known as

The program also includes a series of special courses in ophthalmology and otolaryngology. There will be individual

and sequential courses in both fields. A series of motion picture sessions will be run during the meeting. There will be alumni dinners and luncheons. The sixth annual meeting of the American Association of Eye, Ear, Nose and Throat Society Secretaries, Wednesday evening, October 11, will be devoted to extension study courses for eye, ear, nose and throat societies presented by Dr. William L. Benedict, Rochester, Dr. Gracie, Dr. Dean M. Lierle, Iowa City, and Dr. Albert D. Ruedemann, Cleveland. The American Orthoptic Council will hold an examination Saturday, October 7, at 2 o'clock at the Illinois Eye and Ear Infirmary. The American Board of Otolaryngology will hold its examinations at the Palmer House, October 4-7. Part I of the examination of the American Board of Ophthalmology will be held at the Edgewater Beach Hotel October 5-6 and part II at the Illinois Eye and Ear Infirmary October 7. The American Orthoptic Council and the American Association of Orthoptic Technicians will hold a joint symposium Sunday with the following speakers: Miss Jean Robinson, Memphis, on "Follow-Up in Orthoptics"; Dr. Frank D. Costenbader, Washington, D. C., "Analysis of Failures in the Treatment of Squint," and Miss Louisa Wells, Washington, "Orthoptic Fictions and Misconceptions." Other scientific programs will be concerned with the conservation of hearing, industrial ophthalmology and otosclerosis study group. A feature of the academy meeting will be a symposium on "Head and Face Pain" by Drs. Walter I. Lillie, Philadelphia; Arthur W. Proetz, St. Louis; Bayard T. Horton, Rochester, and Lewis J. Pollock, Chicago.

MEDICAL BILLS IN CONGRESS

Bills Introduced.—S. 2144, introduced by Senator Andrews, Florida, proposes to provide more efficient dental care for the personnel of the United States Navy. It provides for a director of the Dental Corps of the Navy with the rank, pay and allowances of a rear admiral, provides for the establishing on ships and on shore stations of dental services to be administered under the senior dental officer, and authorizes the Secretary of the Navy to provide for a suitable number of dental technicians of appropriate ratings and ranks and for their training, detail, retention, supervision and direction by appropriate dental officers. S. 2163, introduced by Senator O'Mahoney, Wyoming, for himself and Senator Ferguson, Michigan, proposes to incorporate the Medical Women, Army-Navy Club. The objects of the corporation will be (a) to endow a memorial to honor nurses of the Army and Navy who served as officers of the armed forces in World War II, (b) to maintain a domicile for the comfort and service of all women who have served as commissioned officers of the Medical Departments of the Army and Navy, (c) to establish a club to aid in the continuance of the high morale of the medical women of the armed forces, (d) to provide a place of meeting and room accommodations and to promote entertainment for the best interest and efficiency of the medical women officers of the armed services and (e) to engage in such other activities for the promotion of the general welfare of the women commissioned officers as the corporation shall from time to time determine. H. R. 5265, introduced, by request, by Representative Pace, Georgia, provides for the development of better diets and an improved nutritional status for the people of the United States. H. R. 5388, introduced by Representative Bradley, Pennsylvania, proposes that no member of the land or naval forces of the United States shall be required to pay the cost of his transportation from an army or navy hospital in which he is a patient, or from any other hospital or institution in which he is undergoing treatment at the expense of the United States, to another such hospital or institution on the ground that such transfer was made at his own request. H. R. 5402, introduced by Representative Fay, New York, proposes an appropriation of \$3,000,000 to construct a Veterans' Administration general medical and surgical hospital and domiciliary facility in the Borough of Manhattan, city of New York. H. R. 5414, introduced by Representative King, California, proposes to construct in Los Angeles a marine hospital for the accommodation of approximately 300 bed patients.

LATIN AMERICA

Health Activities in Latin America.—DDT Experiments. —The Puerto Rico Insular Health Department is planning a series of experiments with DDT (dichloro-diphenyl-trichloroethane) insecticide to determine its efficiency and effects on human beings, livestock and agriculture, provided permission to purchase DDT can be obtained from the War Production Board in Washington. The department's malaria control bureau is preparing a report on projected experiments with DDT which will be submitted to the War Production Board. Experiments are planned with the insecticide in marshes for the destruction of mosquitoes.

Personal.—Dr. Emilio Mattar, who has been doing post-graduate work at Michael Reese Hospital, Chicago, returned to Brazil July 24. He has received an appointment to set up and direct a metabolism laboratory in the department of medicine of the University of São Paulo.

Medical Congress.—The second Pan American Conference on Leprosy will be held in Rio de Janeiro sometime in 1945, the exact dates to be chosen later.

Program Against Typhus.—The Guatemalan government has signed a contract with the United States for a cooperative campaign of sanitation to end typhus and eliminate malaria from the middle highlands of Guatemala. The New York Times reports that the cost was expected to be \$600,000, of which Guatemala will provide \$300,000 and will borrow an equal sum from the United States to be repaid in four years. The work will be carried out by both Guatemalan and American experts and technicians.

Health in Panama.—An excellent water system is the first reason for the success of public health work in Panama City, Colon and the Canal Zone, says Brig. Gen. Henry C. Dooling, M. C., chief health officer of the Panama Canal. Health conditions in these communities are highly satisfactory, it was stated, and will tend to remain so if the soundness of the water system, which was "hard to surpass," is maintained. Typhoid will be eliminated once sewage disposal facilities are removed from harbors and beaches, General Dooling stated. A joint sewage disposal board, made up of Canal Zone and Panama representatives, is now at work on long range plans for the coordination of sewage disposal in the Sabanas, Bella Vista, Panama City and Balboa districts. General Dooling also stated that Panama's high tuberculosis rate is attributable to poor housing conditions. Good results are expected from the extensive housing projects undertaken by the recently organized Urbanization Bank. The "liquidation" of Panama's rat population would expel another health menace confronting the people of the republic.

FOREIGN

Jeffries Prize Goes to Air Marshal Whittingham.—The Institute of Aeronautical Sciences announced September 3 that the annual John Jeffries Prize for contributions to aeronautical medical research has been awarded to Sir Harold E. Whittingham, Director General, Medical Services of the Royal Air Force.

Nutrition Research Unit.—A human nutrition research unit has been established by the British Medical Research Council, London, with Dr. Benjamin S. Platt as director, Science reports. The unit is already engaged in investigations affecting colonial nutrition and is offering hospitality for study and research to nutrition workers from the colonies. It will also be available to advise colonial governments on technical questions.

Ophthalmic Gold Medal.—The Ophthalmological Society of Egypt announces that a gold medal will be awarded annually for the contribution deemed most valuable that year in the field of ophthalmology. A competitive essay will determine the award, which will be considered at the annual congress of the society. Additional information may be obtained from the Ophthalmological Society of Egypt, Dar el Hickma, 42 Kasr el Ainy Street, Cairo.

Deaths in Other Countries

Sir Hugh Mallinson Rigby, "sergeant surgeon" to King George V from 1928 to 1932. He performed an operation credited with saving the king's life in 1928. Sir Hugh died July 17.—**Dr. Juan Carlos Llamas Massini**, professor of obstetrics, Faculty of Medical Sciences of the University of Buenos Aires, and president of the Society of Obstetrics and Gynecology, Buenos Aires, died July 2.—**Sir Humphry Rolleston**, physician to the late King George the Fifth, died at his home in Surrey, September 24, aged 82.

CORRECTION

Iodized Table Salt to Combat Goiter.—The Brazil Letter published in THE JOURNAL September 9, page 120, under the paragraph "Iodized Table Salt to Combat Goiter," stated that the product shall contain 10 mg. of iodine per kilogram of table salt. This presumably should have been 100 mg. of potassium iodide per kilogram, which conforms with the usual proportions followed in this country.

Aug. 26, 1944.

Questionnaire on the National Health Service

Some months ago the British Medical Association issued a questionnaire to the whole medical profession on the proposed national health service. Forms were sent to 53,728 physicians, and replies were received from 25,435, or 48 per cent. A large number of forms were sent to physicians in the fighting services. The following are the most important questions and a summary of the replies: Is your reaction to the white paper of the government favorable or unfavorable? The replies were 39 per cent favorable and 53 per cent unfavorable; 6 per cent did not know. Will the country's medical service be improved or suffer? Thirty-two per cent thought it would be improved, 12 per cent that it would be unaffected and 44 per cent that it would suffer. In 1943 the representative meeting of the British Medical Association voted that any national health service should be confined to 90 per cent of the public and exclude the 10 per cent upper income group. The white paper proposes that every one should be included but that no one should be required to use it. Should this basic proposal be accepted? It was accepted by 60 per cent and refused by 37 per cent. Should complete hospital and specialist services be available to every one in a general ward? Sixty-nine per cent of the answers were favorable to this. Should a patient who wanted to choose his own hospital or go into a private or semiprivate ward be permitted to pay a "hotel charge" and still receive medical attention under the service? The answers were 41 per cent affirmative and 54 per cent negative. Two out of every three voters approved the principle of health centers. Should the buying and selling of practices be maintained or abandoned on the assumption that adequate compensation is paid to existing owners? Thirty-three per cent were in favor of maintaining this practice and 56 per cent were against it. Thus the replies to the questionnaire reveal a greater difference of opinion than was supposed to exist.

The Problem of the Rheumatic Child

The Cardiac Society and the British Pediatric Association have prepared a joint report on the care of rheumatic children. It states that acute rheumatism is primarily a disease of school age, that means of prevention are not known, and that efficient treatment depends on early diagnosis and methods known to limit cardiac damage. Three measures are proposed: (1) establishment of cardio-rheumatic clinics where the diagnosis can be established early and certainly, (2) organization of hospital schools where children can be treated as long as necessary while education continues and (3) compulsory notification of all cases of acute rheumatism, chorea and rheumatic heart disease. These steps might first be tried in large cities with medical schools where an appropriate staff can be found. The clinic should be held weekly and associated with a key hospital where laboratory facilities are available, the report states. The patients could be used for teaching, it is pointed out. The clinic should undertake supervision and follow-up, which should be continued into adult life. The staff should include physicians experienced in children's and heart diseases and should have the help of an assistant physician or registrar. Besides having access to a laboratory for sedimentation rates, blood counts and biochemical investigations, the clinic should be equipped with the means to measure heights and weights, to screen and x-ray hearts and to take electrocardiograms. The clinic physicians should arrange treatment to minimize cardiac damage, supervise the

life of the children, collect data on prevention, direct adolescents and adults into suitable occupations, and educate doctors in the diagnosis of acute carditis and other heart diseases, the report says.

Hospitals for the treatment of children with cardiac rheumatism should be established throughout the country. The serious results of rheumatic carditis require that all cases of suspected acute rheumatism, chorea and rheumatic heart disease in children under the age of 16 should be made notifiable. A committee should be formed to keep the clinics in touch with one another and to coordinate research.

Proposed Register of Specialists

In this country the status of specialists is well recognized, but they have no legal status apart from that of physicians in general. A special committee appointed by the General Medical Council (which, among other matters, controls medical registration) to consider the formation and maintenance of a register of specialists has issued its report. This recalls that last February the council reaffirmed its view that it is desirable and in the public interest that a register of specialists should be formed and maintained by the council. The immediate object of such a register would be to provide the authorities responsible for the organization of specialists' services as part of the proposed national health service and, in particular, the authorities for making appointments of specialists in that service, with an authoritative means of ascertaining whether or not any particular registered medical practitioner is eligible for appointment. The future object of the register of specialists would be to establish a standard of postgraduate medical qualification and experience for those who can be accepted for registration by the council.

Institute for Research and Teaching of Ophthalmology to Be Established in London

The plan to establish at Oxford University a center of ophthalmic research and postgraduate study has been reported in *THE JOURNAL* (June 17, p. 507). A similar plan has now been formed in London. The council of the Royal Eye Hospital has decided to establish an Institute of Ophthalmology where teaching and research can be carried out systematically and coordinated with the work of laboratories and general hospitals. The institute, with an independent board of governors, will work under the patronage of the Archbishop of Canterbury, the Archbishop of Westminster and other prominent persons. To ensure that the institute is broadly established, panels of advisers have been set up to help in planning and carrying out the work. These include eminent scientists, physiologists, physicians, surgeons and ophthalmologists. The courtesies of the institute will be available to all ophthalmologists, and offers of cooperation will be welcomed.

The F.R.C.S. in Ophthalmology

The fellowship of the Royal College of Surgeons is the highest surgical qualification in England and is held by the leading ophthalmic surgeons, who have obtained it by the same examination that general surgeons undergo. But, in this age of specialism, an innovation has been proposed. The Council of British Ophthalmologists has asked the council of the Royal College of Surgeons to grant a special diploma of the college as a higher diploma in ophthalmology. The council of the college has given this request careful consideration and agrees that a special examination would be more suitable than the usual final fellowship examination for those specializing in this important branch of practice. It is also clear to the council that the present regulations for the "F.R.C.S. with Ophthalmology" are too exacting in that candidates are required to have passed the usual final examination of the fellowship. The council members therefore agree that there should be a special

final examination for the fellowship for those specializing in ophthalmology and that, since the standard would be comparable to that of the usual final examination, successful candidates should rank as fellows of the college, with all their privileges. Under the existing charters the council has no right to make this arrangement, but it is prepared to seek it. It is anticipated that two ophthalmic surgeons will be required on the examination board. It is proposed that they should be fellows of the college. Two other surgical members of the examination board would be selected from the general surgeons on the court of examiners and would take part in some portions of the theoretical examination.

Woman Professor of Obstetrics and Gynecology

Mrs. Bertram Lloyd has been appointed to the chair of obstetrics and gynecology in the University of Birmingham, left vacant by Sir Harold Beckwith Whitehouse, who died when he was president of the British Medical Association. Mrs. Lloyd graduated in science in 1914 and in medicine two years later at Birmingham University. She then became medical officer to the Maternity Hospital and the Midland Hospital for Women. In 1920 she took the fellowship of the Royal College of Surgeons and became obstetric surgeon to the Maternity Hospital and acting surgeon to the Hospital for Women. In 1930 she married Mr. Bertram Lloyd, who is professor of forensic medicine and lecturer on clinical surgery at the University of Birmingham. Mrs. Lloyd was appointed assistant to the chair of obstetrics before succeeding to it.

AUSTRALIA

(From Our Regular Correspondent)

July 17, 1944.

Deficiency of Thiamine in the Australian Diet

The average diet eaten by the Australian is estimated to contain about 1.2 mg. of thiamine daily per "adult male." Many diets are much lower than this, and there are probably few people in Australia whose thiamine intake is up to the National Research Council standard of 1.8 mg. per day for the moderately active man.

The Nutrition Committee of the National Health and Medical Research Council has given consideration to measures designed to increase the thiamine content of the Australian ration. These studies were directed along two lines: (a) the raising of the percentage of extraction from flour and (b) the enrichment of the flour with synthetic nutrients.

The first line of study showed that there were considerable technical difficulties associated with the manufacture of high extraction flour. Most of the flour milled in Australia is "straight run" flour. Milling practice in Australia does not divide the flour into separate types, as is the practice in other countries, nor is the general standard of milling machinery in Australia as good as elsewhere. Many Australian mills fall far short of what is necessary for the manufacture of good flour even at normal percentages of extraction. The redesigning of the machinery for making high extraction flour in Australia would necessitate the use of skilled manpower, which is not at present available. Furthermore, the climatic conditions and the long distances in Australia are not conducive to the long storage of high extraction flour.

The so-called mill offal (bran and pollard) is more than fully utilized in the feeding of poultry and dairy animals, and the production goal for the product of these animals has increased considerably. The estimated requirement of these mill by-products is already in excess of the available supply. New Zealand, moreover, requires about 60,000 tons yearly of bran and pollard.

On the basis of an 80 per cent extraction flour the amount of vitamin B₁ supplied by bread made from this flour would be

about 50 per cent greater than that provided by bread made from the present white flour of 70-72 per cent extraction. The use of an 80 per cent extraction flour would increase the total thiamine intake of the Australian citizen living on an average diet by about 10 per cent. This 10 per cent would come almost entirely from the pollard fraction of the offal. This would mean that up to two thirds of the supply of pollard would be withdrawn and the remaining third would not have the same nutritional value for animal feeding as that now produced. Accordingly, the committee did not feel justified in recommending the introduction of a flour of high extraction (80-85 per cent) for the manufacture of bread in lieu of white flour of 70-72 per cent extraction.

The baking interests in Australia are opposed to the baking of either whole meal or high extraction flour. They fear that such bread, in that it differs from that acceptable to the Australian palate by custom, would tend to be consumed in smaller quantities. Their activities have been directed toward an advertising campaign to encourage the consumption of more white bread. This campaign has been notorious for its misleading, inaccurate statements.

The Nutrition Committee of the National Health and Medical Research Council was opposed to the enrichment of flour with synthetics on the ground that "there is no evidence that vitamin B₁ produces its complete nutritional effect by its own unaided physiological action."

Estimations of the thiamine content of Australian wheat and flour during one season have shown that the thiamine content of Australian wheat is higher than it is in wheats from other countries; but, even so, bread made from Australian flour provides only 0.34 microgram of thiamine per nonfat calory. As it is considered that complete metabolism is achieved only with a ratio of 0.5 microgram of thiamine per nonfat calory, it will be seen that the Australian white bread does not carry sufficient thiamine for its own complete oxidation.

The Australian army in its field bakeries produces bread of either 40 per cent wheat meal or 6 per cent wheat germ. This bread is estimated to provide 43 micrograms of thiamine per ounce. This compares with white bread at 25 micrograms per ounce and whole meal bread at 71.

The Australian army and air force have banned the sale of "ready to eat" breakfast foods by army canteens. This was done as a result of analyses which showed that there was an average thiamine destruction in the factory preparation of 94 per cent in the leading brands. The practice had developed of army units substituting the thiamine rich oatmeal and wheat meal issue by such devitaminized foods. No "ready to eat" breakfast food in Australia is enriched by synthetic nutrients.

The increasing taste and demand for sugar among service personnel also is causing some concern.

Marriages

HENRY L. HARRIS, Los Angeles, to Miss Mary Wallace Austin in Alabama, June 15.

LAWRENCE J. O'NEIL to DR. CORNELIA ST. ROMAIN, both of New Orleans, May 23.

NELSON A. WOLFE to Miss Betty Denny, both of New Albany, Ind., August 24.

EDWARD G. RIVET, New Orleans, to Miss Judith McMahon of Clinton, La., June 10.

JAMES V. KAUFMAN to Miss Elizabeth H. Toye, both of New Orleans, June 3.

JAMES M. BUIE, Mertens, Texas, to Miss Margaret Stell of Irene in July.

VERNON N. BALOVICH, New Orleans, to Miss Sue Fernandez, May 25.

Deaths

Edward Clarence Moore ☉ Los Angeles; University of Southern California College of Medicine, Los Angeles, 1904; clinical professor of surgery at his alma mater; founder member of the American Board of Surgery; member of the American Surgical Association and the American Urological Association; member and past president of the Pacific Coast Surgical Association; fellow of the American College of Surgeons; at one time on the staff of the Mayo Clinic, Rochester, Minn.; during World War I served as major and consulting surgeon in the medical corps, American Expeditionary Forces, stationed at Base Hospital number 26; past president of the state fish and game commission; chief surgeon and a founder of the Moore-White Clinic; on the staffs of the California, Cedars of Lebanon and Good Samaritan hospitals; died July 10, aged 62, of carcinoma of the left kidney with metastasis to the lungs.

Lester Low Watson ☉ Passed Assistant Surgeon, U. S. Public Health Service Reserve, Milton, Mass.; Boston University School of Medicine, 1928; member of the Massachusetts Medical Society; fellow of the American College of Physicians; formerly instructor in medicine at his alma mater; served as visiting physician and secretary of staff, Massachusetts Memorial Hospitals, Boston, and visiting physician, Milton Hospital and Convalescent Home; formerly examiner, tuberculosis division, Boston Health Department; examining physician, Randolph District, Massachusetts Selective Service; formerly chief of the Milton Civilian Defense; recently stationed at the U. S. Public Health Service Hospital, Sheepshead Bay, Brooklyn, where he died June 14, aged 43, of coronary occlusion.

Ralph Farnsworth Harloe ☉ Brooklyn; Long Island College Hospital, Brooklyn, 1918; also a pharmacist; since 1937 assistant clinical professor of surgery at his alma mater; fellow of the American College of Surgeons; past president of the Brooklyn Surgical Society; served as special examiner for the U. S. Civil Service Commission and the U. S. Veterans Bureau in Washington, D. C.; served during World War I; on the staffs of the Sea View Hospital, Staten Island, Long Island College Hospital, Kingston Avenue, Bushwick, Evangelical Deaconess and Bay Ridge hospitals; director of thoracic surgery at the Kings County Hospital, where he died July 31, aged 64, of coronary occlusion.

William Figures Lewis ☉ Colonel, U. S. Army, retired, Pasadena, Calif.; University of Maryland School of Medicine, Baltimore, 1893; entered the army as an assistant surgeon in 1893; became a major in the medical corps of the U. S. Army in 1908, a lieutenant colonel in 1916 and a colonel in 1917; retired Dec. 15, 1922 after twenty-nine years' service; received the Distinguished Service Cross for bravery in action during the Philippine Insurrection; served in the Boxer Rebellion in China and the Spanish-American War; chief surgeon of the Allied Expeditionary Forces in Siberia during World War I; died September 10, aged 78, of arteriosclerotic heart disease.

Michael Milton Lucid, Syracuse, N. Y.; Syracuse University College of Medicine, 1896; member of the Medical Society of the State of New York; member of the House of Delegates of the American Medical Association in 1915; fellow of the American College of Surgeons; served during World War I; colonel in the medical reserve corps of the U. S. Army not on active duty; formerly on the staff of the Cortland County Hospital, Cortland, and a founder of the Homer Hospital, Homer; died in the Hospital of the Good Shepherd, Syracuse University, July 11, aged 75, of lobar pneumonia, generalized arteriosclerosis and acute nephritis.

James Cornelius Austin, Spencer, Mass.; College of Physicians and Surgeons, Baltimore, 1896; member of the Massachusetts Medical Society; past president of the Worcester District Medical Society; chairman of the board of health for twenty-five years and school physician for many years; died July 10, aged 69, of cerebral hemorrhage.

Paul Harold Bikle ☉ Mifflinburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; formerly on the staff of the University Hospital, Philadelphia; served as company surgeon for the Williamsport District of the Pennsylvania Railroad; died in the Harrisburg Hospital, Harrisburg, July 30, aged 65, of coronary occlusion.

James Walter Van Blaricum ☉ Minneola, Kan.; Kansas City (Mo.) Medical College, 1901; for many years member of the school board; died June 4, aged 70, of bronchial asthma.

George Proctor Cooper ☉ Angels Camp, Calif.; Cooper Medical College, San Francisco, 1906; served as county health officer and county physician; chief examiner for the Calaveras County Selective Service Board during World Wars I and II; commissioner, Angels Fire Department; for many years president of the board of education; superintendent of the Calaveras County Hospital; died in St. Luke's Hospital, San Francisco, July 18, aged 64, of carcinoma of the colon.

Channing Ellery Dakin, Mason City, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1899; member of the Iowa State Medical Society; fellow of the American College of Surgeons; served as health officer of Mason City; attending surgeon and chief of staff, St. Joseph's Mercy Hospital; died July 8, aged 68, of carcinoma of the colon.

Alice Mabel Woods Fiddes, Morgan Hill, Calif.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1885; died July 24, aged 83, of arteriosclerotic heart disease.

James Berry Gilbert ☉ Tulsa, Okla.; Mississippi Medical College, Meridian, 1912; served as county physician; on the staffs of the Hillcrest Memorial and St. John's hospitals; died July 4, aged 55.

Fred Thomas Hauser ☉ Purellville, Va.; Medical College of Virginia, Richmond, 1933; on the staffs of the Loudoun County Hospital, Leesburg, and the Winchester Memorial Hospital, Winchester; died July 25, aged 41, of brain tumor.

William James Latimore, Herminie, Pa.; Eclectic Medical Institute, Cincinnati, 1897; examiner of schools and in 1902 school director; died in the Westmoreland Hospital, Greensburg, July 16, aged 72, of peptic ulcer.

John H. Runyon, Seymour, Iowa; College of Physicians and Surgeons, Keokuk, 1890; member of the Iowa State Medical Society; died July 30, aged 77, of coronary thrombosis.

Frederick Parker Scribner, Manchester, N. H.; Dartmouth Medical School, Hanover, 1909; member of the New Hampshire Medical Society and the American Society of Anesthetists, Inc.; on the staffs of the Hillsborough County General Hospital, Grasmere, and the Elliot Hospital; died in Bedford July 17, aged 60, of coronary thrombosis.

Isaac Grafton Sieber Jr. ☉ Passed Assistant Surgeon, U. S. Public Health Service Reserve, Cleveland; Temple University School of Medicine, Philadelphia, 1932; intern and a staff member at the St. Alexis and Glenville hospitals; on the staff of the Booth Memorial Home and Hospital; entered the U. S. Public Health Service in 1942 and was assigned to the Coast Guard in Boston; died August 5, aged 39, of carcinoma of the left lung.

Lewis C. Snell, Neosho, Mo.; University Medical College of Kansas City, 1900; died in St. John's Hospital, Joplin, July 20, aged 79, of myocarditis.

Charles Ira Stephen, Ansonia, Ohio; Starling Medical College, Columbus, 1897; member of the Ohio State Medical Association; past president of the Darke County Medical Society; served in the medical corps of the U. S. Army during World War I; a member of the board of education and for many years a member of the county board of health; on the staff of the Wayne Hospital, Greenville, where he died July 13, aged 70, of carcinoma of the liver.

M. Eugene Street ☉ Glendon, N. C.; College of Physicians and Surgeons, Baltimore, 1893; on the staff of the Moore County Hospital, Pinchurst, where he died July 14, aged 78, of coronary occlusion.

Basil Mitchell Taylor, Portland, Ind.; University of Louisville (Ky.) Medical Department, 1892; member of the Indiana State Medical Association; for many years secretary of the Jay County Medical Society; health officer of Portland; formerly state senator in Kentucky; served as secretary-treasurer of the staff of Jay County Hospital; died July 10, aged 74, of coronary occlusion.

John Quincy Thomas ☉ Conshohocken, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; served two terms as president of the Conshohocken town council and for many years as president of the Mary H. Wood Park commission; a trustee of the Norristown State Hospital, Norristown, for eighteen years; on the staffs of the Bryn Mawr Hospital, Bryn Mawr, and the Montgomery Hospital, Norristown, where he died July 26, aged 69, of cerebral arteriosclerosis.

George S. Trotter, Olney, Ill.; Kentucky School of Medicine, Louisville, 1898; served as president of the board of education and on the inductees examining board during World War I; died July 23, aged 75, of arteriosclerosis.

DIED WHILE IN MILITARY SERVICE

Melbourne Wells Boynton @ Chicago; Rush Medical College, Chicago, 1935; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; served an internship at St. Luke's Hospital; chief resident and later on the attending staff of the Chicago Lying-In Hospital and Dispensary; resident in obstetrics at the Chicago Maternity Center and the University of Chicago Clinics; instructor of obstetrics and gynecology, University of Chicago School of Medicine; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Aug. 26, 1935; began active duty on March 7, 1941, in charge of obstetrics and gynecology at the William Beaumont General Hospital, El Paso, Texas; later promoted to captain, major and lieutenant colonel; chief, medical safety division with headquarters at the Army Air Forces, Office of Flying Safety, Winston-Salem, N. C.; killed in an experimental parachute jump from high altitude at Clinton County Army Air Base, Wilmington, Ohio, August 19, aged 39.

George Kremer Rhodes, San Francisco; Johns Hopkins University School of Medicine, Baltimore, 1915; diplomate of the National Board of Medical Examiners and founder member of the American Board of Surgery; associate clinical professor of surgery at the University of California Medical School; member of the California Medical Association, Western Surgical Association and Pacific Surgical Association; fellow of the American College of Surgeons; associate visiting surgeon, San Francisco Hospital, and assistant chief surgeon, San Francisco Emergency Hospital; volunteer surgeon of the American Ambulance Corps in France during World War I; commissioned a lieutenant colonel in the medical reserve corps of the U. S. Army on Dec. 20, 1940; began extended active duty on May 15, 1942; served overseas with the 30th General Hospital (affiliated unit of the University of California Medical School) and later became surgical consultant in the southern district of the European theater, where he died July 23, aged 54, of coronary occlusion.

Lloyd Thomas Sussex @ Havre, Mont.; Northwestern University Medical School, Chicago, 1926; diplomate of the National Board of Medical Examiners; fellow of the American College of Surgeons; intern at the Wesley Memorial Hospital, Chicago, from July 1925 to April 1927; later fellow in surgery at the Mayo Foundation in Rochester, Minn.; served on the staffs of the Sacred Heart and Kennedy Deaconess hospitals; commissioned a lieutenant in the medical corps of the U. S. Naval Reserve on Feb. 10, 1937, promoted to lieutenant commander on June 30, 1942 and commander on Oct. 1, 1942; spent eighteen months in the South Pacific area, four months at Guadalcanal, some time in New Zealand and was in the battle of Tarawa; had been given honorable mention for having performed operations on 140 wounded men during seventy-two consecutive hours; died in the U. S. Naval Hospital, Farragut, Idaho, June 8, aged 45, of coronary thrombosis.

Martlin Pendry Smith, Erie, Pa.; University of Pittsburgh School of Medicine, 1933; member of the Indiana State Medical Association; specialist certified by the American Board of Otolaryngology; served an internship at the Pittsburgh Medical Center, a residency in obstetrics at the Elizabeth Steel Magee Hospital, Pittsburgh, a residency in eye, ear, nose and throat at the Buffalo General Hospital and the Children's Hospital in Buffalo, and the New York Polyclinic Medical School and Hospital, New York; formerly a member of the visiting staff of the Ball Memorial Hospital, Muncie, Ind.; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on June 2, 1941; later promoted to lieutenant and lieutenant commander; died in the African area on July 5, aged 35, of injuries received in an automobile accident.

Morton Atherton Cundiff, Somerset, Ky.; University of Louisville School of Medicine, 1941; served an internship at St. Joseph Hospital, Lexington; commissioned a

first lieutenant in the medical corps, Army of the United States, on May 26, 1942; began active duty on July 2, 1942; later promoted to captain; flight surgeon in the Air Corps; died in the European theater of operation July 4, aged 29, of injuries received in an airplane accident.

Foster Leonard Dennis @ Dodge City, Kan.; Jefferson Medical College of Philadelphia, 1921; served during World War I; fellow of the American College of Physicians; commissioned a major in the medical corps, Army of the United States, on Feb. 24, 1943; formerly stationed at the Walter Reed General Hospital, Washington, D. C., and formerly attached to the Twenty Second General Hospital; died June 26, aged 48, of cerebral hemorrhage.

Judge William Fuller, Assistant Surgeon Lieutenant (jg) U. S. Navy, Jacksonville, Fla.; Tulane University of Louisiana School of Medicine, New Orleans, 1942; served an internship at the Naval Hospital, where he had been on the staff; drowned at sea in the Atlantic area January 7, aged 28.

Julian Leo Hargrove @ Bartow, Fla.; Emory University School of Medicine, Atlanta, Ga., 1924; served in the U. S. Navy during World War I; superintendent of the Polk County Hospital for many years; commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve on March 28, 1942; executive medical officer of the Deland Naval Air Station; died July 3, aged 46, of injuries received when his automobile struck a bridge abutment on the Deland-Daytona Beach Highway.

Charles Albert McNeil @ Toledo, Ohio; University of Michigan Medical School, Ann Arbor, 1923; completed an internship and served on the staff of St. Vincent's Hospital; served during World War I; commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve on July 2, 1942; senior medical officer of the Naval Officer Procurement in St. Louis; had also been stationed in Chicago; died in the U. S. Naval Hospital, Great Lakes, Ill., July 27, aged 51, of hypertension and heart disease.

Leslie Bertram Roberts, Brooklyn; New York University College of Medicine, New York, 1938; served an internship at the Jewish Hospital and a residency in the Montefiore Hospital for Chronic Diseases and the Bellevue Hospital in New York; formerly a research fellow in medicine at his alma mater; commissioned a first lieutenant in the medical corps, Army of the United States, on Aug. 21, 1942 and began active duty on Sept. 2, 1942; promoted to captain in June 1943; chief flight surgeon, Army Air Base, Bruning, Neb.; killed in an airplane accident in Naper, Neb., August 3, aged 28.

Gregory Albert Skully, Detroit; Wayne University College of Medicine, Detroit, 1937; member of the Michigan State Medical Society; interned at the Eloise Hospital, Eloise; commissioned a first lieutenant in the medical corps, Army of the United States, on June 19, 1942 and subsequently promoted to captain; began active duty on July 4, 1942; flight surgeon in the air corps; in charge of the eye, ear, nose and throat division at the Syracuse (N. Y.) Army Air Base Hospital; died in the Station Hospital, Syracuse, N. Y., July 13, aged 32, of pneumonia complicated by bronchial asthma.

Edwin Theodore Tellman, Palmyra, N. Y.; Rush Medical College, Chicago, 1936; member of the Medical Society of the State of New York; served an internship and residency at the Rochester General Hospital, Rochester; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Nov. 23, 1936; subsequently promoted to captain and major; died in the Letterman General Hospital, San Francisco, July 16, aged 34, of agranulocytosis with generalized hemorrhage and bronchopneumonia.

Ralph Milton Wyatt @ Hiawatha, Kan.; University of Kansas School of Medicine, Kansas City, 1933; served as health officer of Brown County; commissioned a first lieutenant July 21, 1942 and began active duty in the medical corps of the Army of the United States on Aug. 22, 1942; later promoted to captain; flight surgeon; died in an airplane accident in Aldershot, England, June 8, aged 38.

Bureau of Investigation**STIPULATIONS****Agreements Between Federal Trade Commission and Promoters of Various Products**

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

Foster's Wonder 30 Minute Corn and Callous Remover.—This is sold by Stomar Products Company, Kansas City, Mo. In November 1943 the concern and its advertising agency stipulated with the Federal Trade Commission to cease representing that the product promotes healing, and disseminating any advertisement which did not warn that care should be taken not to allow the preparation, full strength, to remain too long in contact with the corn, lest its corrosive action extend to the underlying tissue.

H-B Cough Drops.—The C. A. Briggs Company, trading as H. B. Sales Company, Cambridge, Mass., stipulated with the Federal Trade Commission in November 1943 that it would cease describing its cough drops by the term "Hospital Brand," which might give the erroneous impression that the product is made in accordance with a formula prescribed or endorsed by a hospital. Further, it agreed to cease representing that the cough drops contain vitamin A, that their use will impart the benefits derived from the consumption of that vitamin, or that they purify and soften all hardened places in the throat.

Imperial Lax-101.—This is put out by William H. Braun and Alice C. Braun, trading as Imperial Brands Company, Chicago. A stipulation which they entered into with the Federal Trade Commission in December 1943 provided that they would cease representing that the product is a gentle or mild laxative and will move the bowels easily without irritation to the intestinal walls, that it will change an unhealthful evacuation to a healthful one, that it contains no habit-forming drugs, that delayed evacuation will poison the system and lower bodily resistance and that their preparation will remedy such conditions. Further, they agreed to discontinue any advertisement which did not reveal that Imperial Lax-101 should not be used when abdominal pains or other symptoms of appendicitis are present; provided, however, that such advertisements need only contain the statement, "Caution Use Only as Directed" when the labeling carries a warning to the same effect.

Lax-Aid.—Frank M. Spors and Esther Spors, trading as the Spors Company, LeCenter, Minn., who distribute this product, stipulated with the Federal Trade Commission in November 1943 to discontinue any advertisements which did not reveal that the product should not be used when abdominal pain, nausea or other symptoms of appendicitis are present; provided, however, that such advertisements need only contain the statement, "Caution Use Only as Directed" if and when the directions for use, when appearing in the labeling, contain a warning to the same effect.

Mamie's New Discovery Scalp Ointment.—In December 1943 one Mamie Wilson of Los Angeles stipulated with the Federal Trade Commission that she would cease representing that this product will prevent loss of hair or baldness, counteract conditions causing hair loss, or be a cure for dandruff or other scalp ailments except to the extent that it may mitigate itching of the scalp, that it will nourish or stimulate the hair roots or make the hair grow or take on new life, or will tone the oil glands of the scalp or the blood corpuscles, or have any other effect on the latter.

NR Tablets or Nature's Remedy.—The Lewis Howe Company, St. Louis, which sold this product, entered into a stipulation concerning it with the Federal Trade Commission in November 1943. In this the concern agreed to discontinue any advertising which failed to reveal that the preparation should not be used when abdominal pain, nausea or other symptoms of appendicitis are present, provided, however, that it would be sufficient if the advertising made the statement, "Caution Use Only as Directed" if the instructions for use on the label or elsewhere in the labeling should contain a warning to the same effect.

Othine Face Bleach.—This is put out by the Othine Corporation of Buffalo, N. Y. In February 1944 that concern stipulated with the Federal Trade Commission that it would discontinue any advertisement which did not reveal that the product should not be applied at any one time to an area of skin larger than that of the face and neck; that too frequent applications over excessive periods of time should be avoided; that adequate rest periods between series of treatments should be observed, that the bleach should not be used where the skin is cut or broken, and that in all cases a proper patch test should be made to determine whether the user is allergic or sensitive to the preparation. The stipulation provided, however, that it would be sufficient for future advertisements to contain only the statement, "Caution Use Only as Directed" if the instructions for use on the label contain a warning to the same effect.

Correspondence**QUESTIONABLE VALUE OF VITAMIN C FOR HAY FEVER**

To the Editor:—Almost every year, with the approach of the pollen season, the public becomes repeatedly apprised of some new "cure" or remedy for this affliction. Through the medium of newspapers, magazines and radio such an impression is made on people that they ask their physicians for these drugs or, what is worse, use them themselves prior to obtaining a medical opinion. One year ionization of the nose was popular; then phenol cauterization; a few years ago potassium chloride was the rage. Careful observation by allergists subsequently disproved the value of these remedies.

This year it is vitamin C. My associates and I undertook a study of this work, commencing with the tree pollinating season in April 1944 in the New York area. It subsequently included the grass and early part of the ragweed season. Some persons were pure hay fever sufferers, others had pollen asthma. The two sexes were about equally represented. Ages varied from 4 to 73 years. Occupations were diversified. The average adult daily dose was 500 mg. of ascorbic acid given in divided doses for a two week period.

It is important to know that pollen symptoms may change remarkably during the day. A victim may be in much distress and quickly be relieved spontaneously, depending on the pollen content in the air, which is quite variable during the day. In appraising results, it is therefore necessary to utilize a large enough group of cases, observe them particularly through the peak of the pollen seasons, and make comparisons with at least one previous year. This we carried out on 48 patients.

Our preliminary findings absolutely do not warrant the recommendation of vitamin C in pollinosis, either as the sole measure of therapy or in conjunction with the injection treatment. We are making observations on allergies other than pollinosis, as well as noting the effects of vitamin C on the peak of the ragweed season, but its value on tree, grass and early ragweed sufferers is highly questionable. In my opinion, therefore, vitamin C cannot be regarded as a useful form of therapy in pollinosis.

DAVID LOUIS ENGELSHIER, M.D., New York.
Chief in Allergy, Bronx Eye and Ear Infirmary,
Morrisania City Hospital and Fordham Hospital.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Silicosis Not an "Injury by Accident."—For thirteen years during the winter months Johnson was employed in a rock or stone crushing plant operated in South Dakota by the defendant. Eventually he contracted pneumoconiosis, or silicosis. Later he instituted an act at law against his employer, based on the theory that he had contracted the pulmonary dust disease referred to during the course of his employment because the employer had negligently failed to maintain in its plant an adequate ventilating system or to install exhaust fans and dust chambers or other suitable contrivances for the removal of dust. The employer moved to dismiss the action on the ground that the injury, if any, suffered by the workman was a compensable "injury by accident" under the workmen's compensation act of South Dakota and that consequently any action based on that injury must be instituted under that act and not at common law. The trial court overruled the motion, and the employer appealed to the Supreme Court of South Dakota.

The sole question here involved, said the Supreme Court, is whether or not, under the circumstances, the injury suffered by the workman is an "injury by accident" within the meaning of the workmen's compensation act, which provides that a compensable "injury" or "personal injury" shall mean "only injury by accident arising out of and in the course of the employment, and shall not include a disease of any form except as it shall result from the injury." SDC 64 0102 (4). The complaint filed by the workman describes an injury resulting from repeated inhalations of silica over an extended period of time. In *Frank v. Chicago, M. & St. P. R. Co.*, 49 S. D. 312, 207 N. W. 89, 91, in which a thrombus or clot of blood in the femoral vein was under consideration, in construing the language quoted from SDC 64 0102 (4), *supra*, this court said "Before he can recover it must appear that some mishap, some untoward and unexpected event, occurred without design; that some accidental injury was suffered, traceable to a definite time, place and cause." In *Mellquist v. Dakota Printing Co.*, 51 S. D. 359, 213 N. W. 947, 949, in which an acute heart attack was under consideration, we said "The requirements of *Frank v. Chicago, M. & St. P. R. Co.*, 49 S. D. 312, 207 N. W. 89, 91, have been met, in that the uncontradicted statements of two physicians show that the injury was of a definite, sudden occurrence, directly traceable to a strain." In *Johnson v. La Bolt Oil Co.*, 62 S. D. 391, 252 N. W. 869, this court receded from the view that the cause of the injury must be some unforeseen and unusual operation, act or condition and held that it is sufficient if the injury itself is unexpected. That we did not, by that decision, recede from the view that the injury must be traceable to a definite time, place and cause is implicit in the language of the decision and is made clear in the subsequent case of *Meyer v. Roettie*, 64 S. D. 36, 264 N. W. 191, 194. The record in that case discloses an injury as a result of ingesting bacillus botulinus. It was there said:

We are of the view that a disease may be an "injury by accident" within the meaning of our statute. The exclusion is of any disease which is not an accidental injury or which does not result from such injury. It is generally recognized that accident as contemplated by the workmen's compensation law is distinguished from so called occupational diseases which are the natural and reasonably to be expected result of workmen following certain occupations for a considerable period of time. On the other hand, if the element of suddenness or precipitancy is present and the disease is not the ordinary or reasonably to be anticipated result

of pursuing an occupation, it may be regarded as an injury by accident and compensable The inception of the disease under the evidence in the instant case is attributable to the unexpected and undesigned occurrence of the presence of the poisonous toxin and is assignable to a definite time, place and circumstance. In our opinion death was the result of an accidental injury.

Subsequent to these pronouncements the legislature reenacted the quoted section of the workmen's compensation act as a part of the revision of 1939. It is presumed the legislature intended that this language should be likewise construed as we construed it prior to its reenactment.

The employer contended, however, that the interpretations made by the Supreme Court referred to had been overruled by the court in its opinion in *Hanzlik v. Interstate Power Co.*, 67 S. D. 128, 289 N. W. 589. In that case, said the Supreme Court, we held compensable under the workmen's compensation act encephalitis contracted following a period of exhausting work and exposure. Because the particular work and exposure described in the evidence in that case extended over a period of five days, the employer argues that this court has eliminated the factors of "suddenness and precipitancy" as a condition precedent to the compensability of an injury under the compensation act. That we did not so intend is indicated by our language in that case, for there we said:

Viewing the record in the light of the tests announced in *Meyer et al. v. Roettie et al.*, *supra*, we are of the opinion that findings based upon substantial evidence support the conclusion that claimant's disease constituted an "injury by accident." His collapse came suddenly upon the heels of unusual exertion, exposure and exhaustion as an untoward, unexpected and unanticipated result of pursuing his employment."

The Supreme Court accordingly held that, since the complaint failed to describe an injury attributable to a definite time and cause or circumstance, it did not describe an "injury by accident" within the meaning of the compensation act and that accordingly the trial court was correct in ruling that an action under the common law was properly maintainable. The order of the trial court was accordingly affirmed—*Johnson v. Concrete Materials Co.*, 15 N. W. (2d) 4 (S. D., 1944).

Virginia, Medical Society of, Richmond, Oct. 23-25. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

by parenteral administration, in a critical series of 16 patients with pulmonary tuberculosis. Cases selected were largely those presenting relatively recent exudative lesions in which the prognosis was poor under any form of treatment. The median average daily dose was 1.07 Gm., and the median length of treatment was five and one-half months. No other treatment except bed rest was employed. The degree and rapidity of improvement during promin therapy, as indicated by x-ray appearances, were greater than would have been anticipated in the same group of cases under rest treatment alone. In certain cases the course of the disease was abruptly reversed from progression to retrogression, but in a few instances the disease remained stationary or progressed during seemingly adequate promin treatment. Promin probably exerts a beneficial effect on human pulmonary tuberculosis when the lesions are of recent origin. Few observations have been made on chronic lesions, but it seems unlikely that they would be appreciably affected by promin. The curative action of promin in human pulmonary tuberculosis is not very potent, and promin alone should not be relied upon to effect an arrest. If these conclusions are borne out by further investigation, promin will have a place in the therapy of pulmonary tuberculosis but strictly as an adjunct to other modes of treatment. The potentially serious toxic effects of promin require that the use of the drug be adequately supervised. They also limit the therapeutic dosage. The high degree of solubility of promin facilitates its parenteral use and therefore appears to give promin a definite therapeutic advantage over relatively insoluble compounds in instances of temporary intolerance to oral medication.

- Further Observations on Production of Autolytic Tuberculin. H. J. Corper and M. L. Cohn.—p. 81.

Transient Pulmonary Infiltrations with Blood Eosinophilia.—Loeffler's syndrome, according to Pirkle and Davin, consists of asthma with cough, the occurrence of eosinophilia ranging from 10 to 60 per cent, the presence of a low grade fever accompanied by mild leukocytosis and an elevated sedimentation rate. X-ray examination reveals pulmonary infiltrations in various parts of the lungs, usually in the lower fields. They disappear rapidly and do not cavitate. Loeffler did not stress the possible allergic nature of the condition, but subsequent observers have suggested and sometimes demonstrated that the pulmonary infiltrations are on the basis of an allergy. The authors state that a woman aged 54 presented a history different from some of the other reported cases of Loeffler's syndrome in the absence of asthma and in the long duration of the pneumonitis continued to migrate for eight months. This woman is now employed as a nurse's aid. She continues to be nervous with easy fatigability and a tendency to tachycardia, but chest x-ray films taken at intervals of two months remain clear and there is no eosinophilia. The etiology of the syndrome remains obscure.

Promin in Tuberculosis.—Hinshaw and his co-workers presented in May 1942 a preliminary report on their experiences with promin (a diaminodiphenylsulfone derivative) with special reference to a group of 36 patients who had received supposedly adequate doses for from four to twelve months. The originally described clinical trends have been consistent and progressive on further observation. The results are sufficiently encouraging to justify controlled studies on a large series. Exudative lesions of recent origin appear to be more promising types for chemotherapy than those with caseation, necrosis, cavitation and

fibrosis. The toxic manifestations of promin and related drugs are to be constantly reckoned with but are measurable, reversible and controllable and do not appear to have an adverse effect on the clinical course of tuberculosis. Anemia of considerable degree does not appear to hinder the healing process in tuberculosis. A few patients of this series made striking and consistent gains during a time when the hemoglobin content of their blood, as a result of chemotherapy, was constantly less than 10 Gm per hundred cubic centimeters. The authors also direct attention to the use of promin in the treatment of human leprosy.

Allergy of Central Nervous System.—Clarke believes that symptoms of increased intracranial pressure such as headache, vomiting, dizziness, pressure on the optic nerve, convulsions, hyperesthesia, anesthesia, paralysis and psychosis may occur as the result of an allergic shock. Many cases of migraine, of Ménière's disease and of infantile convulsions are of allergic origin. In 1922 Ward suggested that epilepsy is a manifestation of allergy. Clark examined a large number of epileptic patients from the point of view of allergy and concluded that in some there was an allergic etiology. Favorable results may be obtained if this is discovered early enough. He cites several examples and suggests that epilepsy is a manifestation of various conditions, one of which is allergy. It is improbable that an allergic study will relieve more than 10 per cent of the patients. The mental effects of allergy have received little study, though nervous symptoms are so common in association with the allergic diseases that until recently asthma, urticaria, angioneurotic edema and migraine were thought to be primarily diseases of the nervous system. It is a matter of common experience that the asthmatic child, though amenable normally, becomes irritable during an asthmatic seizure. Insomnia and excessive somnolence also have been overcome by correcting the diet of allergic patients. Though it has been demonstrated that allergic shock can cause mental depression, bewilderment and even active delirium, the psychiatrist has entirely overlooked the possibility of some of the recurrent types of psychoses having an allergic background. When patients with recurring psychoses give a family or personal history of allergic disease, they should be given a thorough investigation of their allergic idiosyncrasies and the appropriate treatment indicated thereby.

Physiologic Analysis of Nature and Treatment of Burns.—Glenn discusses the use of closed plaster dressings in burns. There is no local harm from this treatment. There were no instances of injured circulation. The prompt return of function of a part immobilized in plaster over prolonged periods has been one of the most gratifying features. The treatment is comfortable. The plaster dressing is easy to apply to burns of the extremity. The slight after-care is one of the chief advantages. Pain or discomfort in an encased extremity occurring twenty-four to thirty-six hours after application of the dressing was relieved by elevation of the part. After minimal cleaning and débridement and without breaking blisters, two layers of sterile gauze are laid over the burned surface extending above the area to be covered by plaster. If fingers are involved they are enclosed separately in the gauze. A thin sheet of roller plaster bandage is then applied to the part without pressure, extending over the end of the extremity and 2 to 4 inches above the burn. In mild burns the encasement is removed in seven to fourteen days. In more severe burns it may be left in place for as long as four weeks.

Nutritional Care in Extensive Burns.—Co Tui and his collaborators deal with the nutritional care of 3 cases of thermal third degree burns of, respectively, 10, 30 and 50 per cent of the body surface. The patients were given high caloric and high nitrogen feedings in the form of dextrimaltose and amigen. The nitrogen balance was followed throughout convalescence and the plasma proteins and body weight were determined periodically. All 3 patients were maintained in an excellent nutritional state. There seemed to be a mathematical relationship between the extent of surface burned and the amount of nitrogen required to maintain nutrition. Transfusions were reduced to a minimum. Preparations such as amigen seem to be better tolerated and utilized than natural protein food and appear to be the solution to the problem of nutritional care of severe cases of protein drain. The development of shock following immediately on the first skin grafting is a phenomenon which may have an important bearing on the safety of this procedure in extensive burns. Theoretically it is to be expected that in patients undergoing severe protein loss with protein synthesis barely keeping up with the loss the opening up of new areas of the skin surface, with resulting increase in exudation and bleeding, would readily lead to the development of shock. If this explanation is correct, patients in this condition should have no skin grafting attempted unless the protein nutrition has been improved and measures for the therapy of shock are at hand.

Autoinoculation of Eyelids with Vaccinia.—Klunzinger reports the case of a boy aged 8 who developed redness and swelling of the lids of both eyes three days after he had been vaccinated on the right arm. Examination a week after vaccination revealed severe redness of both eyes, swelling and induration, with several ulcerations along the margins, and moderate mucopurulent discharge. There was a nontender swelling from eye to ear bilaterally. A tentative diagnosis of vaccinia reaction was made. Irrigations of boric acid were made every hour during the day, together with application of hot compresses for twenty minutes three times a day. Under this treatment there was decided improvement in five days. The patient was discharged, with instructions to use hot compresses three times a day followed by instillation of aqueous solution of metaphen (1:2,500). Sulfadiazine was used for a short time, since the diagnosis was at first questionable. Its use was discontinued after examination of smears revealed no causative organisms, and its effect was probably only to reduce the febrile reaction. Although ocular complications after vaccination are uncommon, the possibility of their occurrence should be remembered. Lesions of the lids and conjunctiva have been found to run a self-limited course, healing in seven to ten days with no sequelae. Corneal involvement, however, requires a much longer period for healing, and visual impairment often results. It is of the utmost importance to prevent corneal involvement.

- Syphilis of Tendon of Biceps and of Olecranon Bursa.**—Schrager's patient, aged 61, gave a long history of pain in different joints which had been diagnosed repeatedly as rheumatism and arthritis. A 4 plus Wassermann reaction years before led to treatment with neoarsphenamine and bismuth compounds

but the treatment was discontinued when jaundice developed. The patient presented a tumor mass in the upper part of the arm. Operation revealed a tumor mass in the tendon sheath of the long head of the biceps muscle. It was removed together with a few strips of tendon and its sheath, which were red and frayed. An olecranon bursa the size of a large walnut was present over the right elbow. It had a thick capsule. The contents of the bursa were exactly like those found in the tendon sheath of the biceps muscle. Both wounds healed by primary intention. Microscopic examination of the tumor mass revealed changes compatible with a syphilitic granuloma, and the olecranon bursa showed a picture characteristic of a syphilitic gumma. Spirochetes were found in the granulation tissue. The author thinks that syphilis of tendons and bursas should be suspected more often in the diagnosis of tendinitis and bursitis.

Antigenicity of Catgut.—Hopps attempted to determine whether or not a state of hypersensitivity to catgut can be induced. It was considered that catgut per se, because of the probable denaturation of protein and the chemical alteration sustained during preparation and because of its relative insolubility, is a poor antigen. Sheep serum or sheep intestine might be more effective in stimulating the formation of antibodies to catgut than catgut itself. For these reasons the following materials were used as antigens: (1) plain surgical catgut, (2) sheep intestine, (3) sheep serum. The author produced hypersensitivity to catgut in rabbits and guinea pigs, as shown by positive cutaneous reactions, positive reactions to catgut implanted in the anterior chamber of the eye and demonstration of humoral antibodies (precipitins, agglutinins, complement fixing antibodies and anaphylactins) in vivo and in vitro. Catgut, sheep intestine or sheep serum is capable of inducing this hypersensitive state. In addition to antibodies which will react with either catgut or sheep serum, catgut stimulates the production of antibodies specific for itself. These antibodies specific for catgut may also be specific for collagen or for mucoprotein. Heterophile antibodies do not react with catgut.

Effect of Sensitivity to Catgut on Reaction of Tissues to Catgut Sutures.—These experiments were designed to evaluate the effects of hypersensitivity to catgut on the reaction of tissues to catgut sutures and on the healing of surgical wounds repaired with catgut. Hopps observed evidence of slightly heightened reaction of the tissues to catgut sutures in animals which were hypersensitive to catgut. There was, however, no appreciable difference between normal rabbits and rabbits sensitized to catgut in the rate of dissolution or digestion of catgut sutures during the critical period of healing of wounds. There was no significant difference between normal rabbits and rabbits sensitized to catgut in the healing of laparotomy wounds repaired with catgut sutures. The absence of significant allergic reaction to catgut in the wounds of animals sensitized to catgut is attributed to the relative insolubility of catgut sutures.

Delayed Healing and Disruption Produced by Local Allergic Reaction.—Hopps directs attention to Auer's phenomenon of "local autoinoculation of the sensitized organism with foreign protein." It is generally accepted that disruption of the wound is more prone to occur when an abdominal operation is performed in the presence of preexisting infection, such as pelvic abscess or peritonitis. Although this increased incidence of breakdown of the wound may be in response to direct infection of the wound, the possibility of yet another mechanism appears. In the presence of a well localized infection the patient may be assumed to have a rather high degree of immunity or sensitivity to the specific infectious agent and a high humoral antibody titer. As the result of operative manipulation of such a localized infectious lesion an appreciable amount of dead or living bacteria and their products may be forced through the protective barrier of granulation tissue to enter the general circulation. Under these conditions all of the necessary requirements for the development of an Auer reaction would be fulfilled: (1) the surgical wound, providing a localizing lesion; (2) the chronic infection, stimulating a high humoral and tissue antibody titer, and (3) manipulation of the localized infectious process, allowing for the introduction of specific antigen into the blood stream. Experiments demonstrated that the healing of laparotomy wounds is profoundly altered in rabbits previ-

ously sensitized in which specific antigen is reinjected post-operatively. The most obvious explanation is that a local anaphylactic reaction plays a predominant part. Other possibilities to be considered are a direct or indirect effect of general anaphylaxis and local formation of antibodies. The author concludes that local allergic reaction at the site of a surgical wound will delay healing and encourage disruption. The mechanism of such delayed healing appears to rest in a failure of the maturation of macrophages, with resultant failure in the production of the reticulum and collagen.

Carbon Tetrachloride Poisoning.—Konwaler and Noyes add 3 more cases of poisoning from carbon tetrachloride to those reported by others. The 3 men drank heavily over the weekend and reported for duty Monday morning with "hang overs." They worked from 8:30 a. m. to 11:30 a. m. in a poorly ventilated compartment. Three other men, who had not been drinking liquor recently, were also working in the same compartment. The men were cleaning machinery with rags soaked in carbon tetrachloride. They had volatilized approximately 1½ quarts of the liquid in three hours when they noticed that the smell of the vapor became quite heavy. Only 1 of the men developed symptoms during the period of exposure. One patient, who later died, first felt sick at 10 a. m. The second victim felt well until 6:30 that evening. The third man had left the compartment frequently and had been exposed much less than the first two. He showed no symptoms of poisoning until the following morning. The three nonalcoholic workers developed no symptoms and continued at their duty. The 3 cases illustrate three grades of severity of carbon tetrachloride intoxication. Carbon tetrachloride is a potent renal poison, resulting in severe cases in acute toxic nephrosis with uremia. Hepatitis is also found but is not severe. Alcohol ingestion prior to exposure assumes a synergistic role.

Simple Office Test for Uterine Cancer Diagnosis.—Ayre points out that in many cases intensive study of several smears is required to arrive at a correct diagnosis when the smears are taken directly from the vagina. He suggests a modification which consists in taking a smear directly from the external os of the cervix. Here the concentration of cancer cells is greater. In Ayre's series of cases, smears from the vagina were compared with smears from the external os, and in both cervical and fundal carcinoma a much greater concentration of cancer cells was consistently present in smears from the cervix. The vaginal smear test for cancer may be con-

sidered a surface biopsy of the cells and cell clumps being shed by the genital tract. The finding of cancer cells in these secretions would appear to be strong presumptive evidence of cancer. The mere finding of the cells does not always point to the origin of the growth. Since malignant growths of the genital tract are chiefly cervical or fundal, these sites should be the first to be subjected to biopsy. Diagnosis of cancer cells in smears should be confirmed by biopsy before operation or radiotherapy. At the author's clinic 40 cases of uterine cancer were proved by biopsy, and of these 38 showed cancer cells in the smear.

Weil's Disease.—Patterson reports observations on 37 cases treated by him at Olaa Hospital between October 1941 and November 1943. In the Olaa area of Hawaii this disease is essentially an occupational one, occurring principally in young cane cutters. The first symptom in half of the patients was headache. All the patients had loss of appetite and generalized malaise, with 50 per cent having more pain in the calf muscles than elsewhere. Nineteen patients had chills and 13 vomited before admission. All patients had eye symptoms such as conjunctivitis and scleritis, which is the most important manifestation in this disease. All patients were listless and 36 had muscle weakness. Jaundice was present on admission in only 7 patients and developed later in only 9 others. Weight loss averaged 11½ pounds. The average peak temperature was 102.8 F. Twenty-nine patients showed albumin in the urine, 18 showed cells of some kind in the urine and only 1 showed casts. Repeated blood serum agglutination tests are the most reliable laboratory procedure. All patients had positive blood serum agglutinations for *Leptospira icterohemorrhagiae* in dilutions of 1:300 or more. The treatment of choice is whole blood transfusions from convalescent patients. Otherwise the treatment is largely symptomatic. Sulfathiazole and sulfadiazine seem ineffective. The medical profession and industry in the territory should cooperate in the development of a vaccine to be used in the immunization of field workers, and possibly the entire population, against Weil's disease.

Thiourea in Thyrotoxicosis.—Paschkis and his associates report their experience with the use of thiourea and thiouracil in 21 cases of thyrotoxicosis. They found that thyrotoxicosis can be suppressed with either drug. Thiourea proved to be more toxic and was discontinued as soon as thiouracil became available. Toxic manifestations from thiouracil, consisting of cutaneous eruption, fever, arthralgia, leukopenia and jaundice, were observed in 3 cases. Improvement was usually noticeable after from four to six days of treatment, with complete suppression of thyrotoxic manifestations after two to three weeks. In most cases 1 Gm. of thiouracil was effective, but in 3 instances no response was achieved with 1 Gm. and full effect required 2 Gm. Thiouracil was used for preoperative treatment in 3 cases, the preoperative and postoperative course being satisfactory in 2 and death in thyroid crisis occurring in the third,

in which iodine also had been administered preoperatively. The drug proved particularly valuable in cases in which operation was deemed inadvisable. An attempt was made to establish a permanent maintenance dosage level rather than to employ intermittent treatment. After full effect was achieved, doses as small as 0.1 to 0.2 Gm. daily proved satisfactory. Evidences of myxedema developed in 2 cases and subsided after the drug was temporarily discontinued.

Histamine for Ménière's Syndrome.—Turvey reviews the results of treatment with histamine in 36 cases of Ménière's disease. Four of the patients had meningovascular neurosyphilis and received no other treatment except malaria and chemotherapy. They made an excellent recovery. Sixteen have been treated by histamine intravenously with subsequent subcutaneous injections of histamine, phenobarbital orally and occasionally ammonium chloride. Of these 6 have had no attacks of vertigo

for periods varying from one to three years, 5 are improved and 5 are unimproved. Of the remaining 16 patients who were treated with the Furstenburg regimen, consisting of a low sodium chloride diet and ammonium or potassium chloride orally as well as phenobarbital, 3 have been cured for periods varying from one to five years, 4 are improved and 9 are unimproved. Histamine is not a specific and is only a useful adjunct in therapy which frequently fails. Surgery should always be a last resort to be delayed as long as possible.

Relationship of Beriberi and Poliomyelitis.—McCormick made comparisons between beriberi and poliomyelitis during the Toronto poliomyelitis epidemic of 1937 and has arrived at the hypothesis that poliomyelitis can depend largely on a B avitaminosis. The modern conception of the virus of poliomyelitis, which makes of it a chemical substance of known molecular size rather than a living organism, demands a revision of the interpretation of the experiences of Flexner regarding the specificity and transmissibility of the disease. It would then be necessary to envisage the possibility of the endogenic origin of the virus. The paralysis of poliomyelitis could depend directly on a severe deficiency in vitamin B₁, which in turn would depend on certain factors of activation of the general metabolism and the augmentation of the organism's need for the vitamin. These factors will include febrile conditions, age, sex, atmospheric conditions and physical overexertion at play, work or pregnancy. Thus, poliomyelitis becomes a clinical form of avitaminosis rather than a specific autonomic disease. The virus becomes a biochemical product of the pathologic process itself and, although it may be capable by catalytic action on the nervous system to reproduce paralysis in the laboratory animal, it must not inevitably be considered as a transmitting agent of the disease in ordinary circumstances. It is possible that a substance identical with the virus can be obtained from the nervous system of patients with beriberi. The term poliomyelopathy expresses the nature of the disease better than poliomyelitis.

Paroxysmal Tachycardia in Infant.—Vezina describes 3 successive attacks of paroxysmal tachycardia in an infant. The first attack occurred when the infant was 6 weeks old after having been in his perambulator for three hours under a hot July sun. When taken from his perambulator the child was extremely pale and had a rapid respiration. Heat stroke was thought of, but when severe symptoms persisted the child was hospitalized and a diagnosis of paroxysmal tachycardia was made and medication with digitalin was begun at once. At the end of fourteen days the child was discharged from the hospital apparently entirely well. About two months later the child was hospitalized again. At this time the heart action was so rapid that the beats could not be counted on auscultation. Electrocardiography revealed a sinus tachycardia of from 330 to 350 beats a minute. At the age of 7 months the child had a third attack. During the second and third attacks digitalin was given again, but, while the fortunate development during the first attack must be attributed to oral medication with digitalin, this effect of digitalin was less evident during the second and third attacks. It was impossible to determine the cause of this paroxysmal tachycardia. It is characterized by the sudden appearance of polypnea accompanied by cyanosis. Hepatomegaly is pathognomonic. The author is convinced that paroxysmal tachycardia will be discovered more often in infants if electrocardiography is used more often in pediatrics.

Sulfaguanidine for Prophylaxis of Sonne Dysentery.—Yannet and his collaborators showed the effectiveness of sulfathiazole in a previous outbreak of Sonne dysentery in a home for mental defectives. However, the sulfonamide did not curtail the period during which the organism could be recovered by rectal culture. On the contrary, there was evidence that this period was prolonged when compared with untreated controls. It was hoped that the administration of a poorly absorbed drug, such as sulfaguanidine, might correct this defect. A renewed outbreak of Sonne dysentery two years later (1943) gave the authors an opportunity to test the value of sulfaguanidine for reducing the length of the carrier state. The cases of bacillary dysentery were confined to four cottages housing from 40 to 70 inmates each. A total of 29 cases occurred, representing from 10 to 20 per cent of the inmates of the respective cottages involved. The Sonne organism was isolated in every case of acute dysentery. The 29 cases were divided into two groups, one consisting of 18 cases in which sulfaguanidine was administered for seven days; in the remaining 11 cases, the drug was administered for fourteen days. The number of days before the first of the consistently negative cultures was obtained is not significantly different from that in the group in which no specific drug therapy was given. It is felt that the dose used, roughly one fourth of that recommended for therapeutic purposes, might have been inadequate. In two of the cottages it was possible to carry out controlled experiments on the possible prevention of bacillary dysentery by means of sulfaguanidine.

Presence of Poliomyelitis Virus During Winter.—Ward and Sabin report the recovery of poliomyelitis virus in January and February 1942 from the intestinal discharges of 2 poliomyelitis patients, 1 paralytic and the other nonparalytic, and from those of a healthy sibling of each patient who lived on the outskirts of Cincinnati. This isolation of the virus in the winter establishes the occurrence of the disease at that season. This finding has been confirmed by the recovery of virus in February 1942 from the stool of a paralytic patient in Bridgeport, Conn. The epidemiologic implications which suggest themselves are that: 1. Poliomyelitis may occur throughout the year, but its greater incidence during the summer and fall months may be related to opportunities for wider dissemination of virus. 2. It would seem possible that poliomyelitis, like typhoid and dysentery, may be transmitted by any of the several methods whereby infective particles derived from human excrement find their way to the susceptible human host. 3. The patient and the healthy carrier may constitute reservoirs of virus during interepidemic months.

**"Cellophane" for Treatment of Burns. J. Farr.—p. 749.
Symptomless Enlargement of Esophagus. J. L. D'Silva.—p. 751.

Dangers of Sulfonamides in Ear Infections.—Dingley advances the following suggestions for guidance in treatment of otitic infections: Sulfonamides will never take the place of necessary surgical drainage. Treatment of acute suppurative otitis media by a sulfonamide should be reserved for the period after incision of the membrane and bacteriologic investigation. If the fever is maintained, the appropriate sulfonamide may be used in full dosage (day and night) but not after the end of the second week. After two, three or four weeks the condition of the ear, if still actively suppurating, is again becoming one that potentially requires surgical drainage, this time of the mastoid; and signs and symptoms justifying intervention must not be masked by the administration of sulfonamides, which at best will rarely reach the local area but will distort the clinical picture as a whole. Wholesale use of sulfonamides in otitic infections is to be deprecated. If a sulfonamide has been given before drainage, the most valuable help in assessing the beneficial effect of the drug is gained by examining the drum head frequently. If this continues to bulge, myringotomy should not be delayed; for the condition, which otherwise appears to be improving, is in reality becoming more perilous. Persistence of deafness is also a strong indication that all is not well. Patients taking sulfonamide drugs sometimes do not acquire any resistance of their own to the infection with which they are contending, and it would seem that recurrences are more likely in these cases, which, in addition to developing no immunity to the infection, may find that the micro-organism has become sulfonamide resistant. It is needless to emphasize the uselessness and danger of giving inadequate or erratic dosage of sulfonamides.

"Cellophane" for Treatment of Burns.—Farr directs attention to the "cleansing, rest and compression" treatment of burns advocated by Allen and Koch and by Siler. He describes a modification of this method, which consists in an occlusive dressing medicated with sulfanilamide through which the burned area may be easily inspected. This is achieved by the use of "cellophane" and sulfanilamide ointment. Using general anesthesia the intact skin surrounding the burned area is thoroughly cleaned with white soap and water, and then the toilet of the burned area is carried out with isotonic solution of sodium chloride. The medicated sheets of cellophane are then applied so that each overlaps the other for about an inch. These sheets adhere to one another and to the intact skin, and the entire burn is embraced in an envelop that permits of easy inspection and prevents contamination. Next, perforated oiled silk is wrapped around the cellophane to prevent the wool from adhering to the dressing. After forty-eight hours the burn is inspected. The cellophane may be blistered by collections of serum. Any such bullae are trimmed away with scissors and the area affected gently cleaned with saline swabs and another sheet of cellophane applied. This transparent dressing adheres lightly to healed burned areas but if carefully removed does not damage the delicate new epithelium. The cellophane does not adhere to the unhealed areas, so that damage to the tissue, if the dressing must be changed, is minimal. The cellophane sheets may be medicated, sterilized, and stored for immediate use when needed. It is suggested that the application of a powdered sulfonamide to the burn or wound, followed by the immediate application of cellophane sterilized by boiling, offers many advantages as a first aid measure. It permits of easy

and painless inspection of the burn when the ultimate treatment has to be decided and does not prejudice the form of treatment to be adopted. It would prevent contamination and be bacteriostatic to infection already present in the burn.

- Acute Otitic Barotrauma—Clinical Findings, Mechanism and Relationship to Pathologic Changes Produced Experimentally in Middle Ears of Cats by Variations of Pressure. E. D. D. Dickson, J. E. G. McGibbon and A. C. P. Campbell.—p. 465.
*Radon Treatment for Otitis Due to Barotrauma (Preliminary Report). E. P. Fowler Jr.—p. 489.

Radon Treatment for Otitis Due to Barotrauma.—Fowler says that at a U. S. Army general hospital in England attempts have been made to treat and prevent otitis due to barotrauma with radon. It was apparent that the men most susceptible to recurrent otitis media were those with large bands of lymphoid hyperplasia in their lateral pharyngeal walls. When these were present in aviators it seemed to predispose particularly to so-called aero-otitis, with high altitude flying or with dive bombing. Earlier, in his practice in New York the author had used two 25 mg. capsules of radium to shrink down excessive lymphoid tissue about the eustachian tubes of children, using the same dosage recommended by Crowe and his associates, who used radon for the same purpose. Radon was obtained in England and 150 millicuries was placed in two capsules and inserted along the floor of the nose and left in place for twenty-six minutes the first day. This gave a dosage of 66 milligram hours to the entire nasopharynx, a dosage equivalent to the 2 Gm. minutes recommended by Crowe. If the patient had a cold 33 milligram hours was given, and if there was no reaction in two or three days the remaining 33 milligram hours was applied. In the past year 127 men of the air force and the ground force have been given treatment of 66 mg. hours, repeated every three to six weeks up to four or more treatments. There is rarely improvement before the third treatment if 66 mg. hours has been used. The dramatic effect on fliers was not surprising, for it is well known that lymphoid tissue is highly susceptible to radiation and most of the fliers had only a small amount to shrink away. This small amount apparently is enough to clog their eustachian tubes if they fly high or change altitude rapidly. Once they are unable to clear their tubes while descending, edema develops in the middle ear with more or less fluid and they may be grounded from two days to several weeks with aero-otitis. The radon apparently facilitates the normal function of the tube if lymphoid hyperplasia has interfered with their proper opening and closing. It puts previously grounded airmen back in the air, even when they have had repeated severe otitis from barotrauma.

- *Primary Cancer of Liver. M. Valdés Ruiz, A. Zamanillo and E. Salar Luis.—p. 227.

Primary Cancer of Liver.—According to Valdés Ruiz and his collaborators the frequency of primary cancer of the liver without cirrhosis, as reported in the literature, is 1 in 1,000. The symptoms are those of constant epigastric pain which radiates to the right shoulder, loss of appetite, nausea, vomiting, insomnia, headache and acute progressive emaciation. There are progressive uniform enlargement and hardening of the liver, ascites and in rare cases enlargement of the spleen. Primary cancer of the liver without cirrhosis can be differentiated from either primary cancer of a cirrhotic liver or secondary hepatic cancer by the rapid enlargement of the liver, its firmness, a smooth hard border on palpation, moderate ascites and the acute course of the disease, which varies between four and five months after the onset of the symptoms. Cancer hepatoma as found at necropsy is either massive or nodular. The histologic preparations of the liver in cases of nodular cancer show infiltration of the liver parenchyma by cords of cancer cells. Morphologic changes of the liver cells, mitosis and a large number of atypical cells and large cancer cells are observed.

Book Notices

Hydronephrosis and Pyelitis (Pyelonephritis) of Pregnancy: Etiology and Pathogenesis. An Historical Review. By H. E. Robertson, M.D., Section on Pathologic Anatomy, Mayo Clinic, Rochester, Minnesota. Cloth. Price, \$4.50. Pp. 332, with 11 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

This historical review of hydronephrosis and pyelonephritis of pregnancy is a rare book. The author, a pathologist at the Mayo Clinic, became interested in the subject when many years ago he began to observe at postmortem examinations of pregnant women that the ureters and renal pelvis were dilated. As a result of this interest he read and thoroughly analyzed practically every article and book written on the disturbances of the urinary tract in pregnancy. Throughout the text and the numerous pithy footnotes, there is abundant evidence that the author took nothing for granted. He delved into all the original source material published and gives the impression of having read almost every word of the 974 references which are listed in the back of the book. The author points out errors made even by recognized authorities. He shows how often erroneous statements have been reproduced by writer after writer who did not take the trouble to check the original quotations or references.

The only unfavorable criticism offered is that the author should have devoted more space to the subject of treatment. In reality there is only one paragraph, a third of a page long, at the end of the conclusions of the book. Perhaps it is because the author is a pathologist that he refrained from doing this, but he accomplished his task of discussing dilatation and infection of the ureters in pregnancy so admirably that he would have handled the treatment just as satisfactorily.

In the brief but excellent conclusions the author summarizes all the important knowledge we possess about the etiology, anatomy, pathology and bacteriology of hydronephrosis and pyelonephritis of pregnancy.

This is one of the most discerning books, and if any physician, be he obstetrician, urologist, pathologist or general practitioner, wants a real treat, he should read it all the way through. The author is to be highly complimented on his achievement, which represents an enormous amount of hard work. The publishers also have done their part beautifully.

The Dental Treatment of Maxillo-Facial Injuries with Supplementary Material on Cases and Techniques. By W. Kelsey Fry, M.C., M.R.C.S., L.R.C.P., Consulting Dental Surgeon to the Royal Air Force, P. Rae Shepherd, L.D.S., R.C.S., Dental Surgeon, East Grinstead Maxillo-Facial Unit, Alan C. McLeod, D.D.S., B.Sc., L.D.S., Dental Surgeon, East Grinstead Maxillo-Facial Unit, and Gilbert J. Parfitt, M.R.C.S., L.R.C.P., L.D.S., Dental Surgeon, East Grinstead Maxillo-Facial Unit. With foreword by Professor F. R. Fraser, M.D., F.R.C.P., Director General, Emergency Medical Service, and a section on Fractures of the Middle Third of the Face by A. H. McIndoe, M.Sc., F.R.C.S., F.A.C.S., Consulting Plastic Surgeon to the Royal Air Force, Surgeon-in-Charge, East Grinstead Maxillo-Facial Unit. Fabrikoid. Price, \$6.50. Pp. 434, with illustrations. Philadelphia & Montreal: J. B. Lippincott Company, 1944.

During this war the English have had extensive opportunities for the study and treatment of maxillofacial injuries. The employment of common sense with basic principles is noted throughout the book, together with the fact that a wounded patient is being treated rather than an injury with a patient attached to it. Although the chapter on anatomy is much too brief, the excellent description of the muscle pull and its relation to the type of fracture compensates in some degree. The chapter on radiology fills in some measure the need for roentgenology of the facial bones. It is most practical and replete with plates and diagrams. The section on pathology is a welcome addition in a treatise on maxillofacial injuries. Both students and specialists could well profit by reading and rereading it. The authors belong to the school that advocates removal of teeth in line of fracture. An opposite school holds that such teeth should be removed only when there is an indication of trouble, that the tooth should be retained for better approximation of the bone fragments.

Much emphasis is placed on the cast cap splint for fractures of the mandible. This method seems to find greater favor

among our English colleagues, whereas the Gilmer method of wiring (or one of its modifications) is more extensively used in the United States.

The chapter on technic of impression taking and construction of splints is very detailed and most explicit.

The section on field and preliminary hospital treatment of battle casualties can be read with advantage by all medical men engaged in front line action. It is practical and contains much good common sense.

Physiology is stressed throughout the book in connection with treatment.

The supplement with case studies is explicit and instructive, not only for war injuries, but also for maxillofacial injuries occurring among the civilian population during peacetime. The book is profusely illustrated with excellent diagrams and photographs. The reproductions of the roentgenograms are, however, not as clear as they might be.

Artificial Pneumothorax in Pulmonary Tuberculosis (including Its Relationship to the Broader Aspects of Collapse Therapy. By T. N. Kafferty, M.D. Introduction by Henry Stuart Willis, M.A., M.B., Superintendent and Medical Director William H. Maybury Sanatorium, Northville, Michigan. Cloth. Price, \$4. Pp. 192, with 26 illustrations. New York: Grune & Stratton, 1944.

This book provides a discussion of collapse therapy of pulmonary tuberculosis, with special reference to artificial pneumothorax. The author believes that the old practice of attempting artificial pneumothorax in every case before considering surgery, particularly thoracoplasty, should be abandoned and that persons whose disease is so extensive as to require permanent collapse, those with serious pleural infections and those with bronchial tuberculosis should have extrapleural thoracoplasty performed as the primary procedure.

The author believes there is general agreement on the indications for artificial pneumothorax under the following conditions: (1) patients with disease which continues to progress in spite of the usual care; (2) those with cavities and tubercle bacilli in the sputum which do not come under control promptly by bed rest; (3) extensive disease with cavity which could not be expected to be brought under control by the so-called more conservative methods; (4) those with predominantly exudative disease that does not regress after a liberal period of bed rest or bed rest and phrenic paralysis.

Contraindications to artificial pneumothorax which the author considers permanent are (1) a large apical cavity, (2) extensive destruction, (3) the fibrous or shrunken lung and (4) broncho-stenosis. Contraindications which may be temporary or permanent are (1) active bronchial tuberculosis without pronounced stenosis, (2) tuberculous pneumonia and (3) primary tuberculosis. Tuberculous complications, such as laryngitis and enteritis, do not contraindicate artificial pneumothorax except when they are terminal manifestations. Compensated heart disease is not a contraindication unless the tuberculosis is extensive and bilateral. The author wisely points out that in cases of complication the decision concerning pneumothorax can be made only at the bedside.

A liberal point of view is taken on the future possibilities of ambulatory artificial pneumothorax. For example, when all the citizens of the nation are examined and those are found who have recently developed minimal or moderately advanced tuberculosis, so many would need treatment that it would be economically unsound to provide sufficient bed capacity for them. Moreover, if this capacity should be provided it would not long be needed if the intensive program of finding cases was continued. Ambulatory pneumothorax would aid substantially in solving this problem.

In this connection one wonders why the author completely omitted the tuberculin test and emphasized the use of mass radiography in case finding. The tuberculin test is a far better criterion of the tuberculosis situation in any community than the x-ray film. Probably this omission is because he assumes that any physician would have definitely established a diagnosis of tuberculosis before instituting collapse therapy in any form. Unfortunately, many persons are having artificial pneumothorax instituted with diagnoses made on the basis of x-ray shadows and in the total absence of our only two specific findings in

tuberculosis, namely the tuberculin reaction and the recovery of tubercle bacilli.

The pros and cons of instituting artificial pneumothorax in all cases of minimal tuberculosis are discussed. Various other surgical procedures are discussed, such as external drainage of pulmonary cavities, lobectomy and pneumonectomy.

The book contains 195 references and a good index. The author is to be congratulated on having brought together so much valuable information and treating it so adequately and fairly in such small space. This book should be read by all physicians and studied carefully by those who treat chest diseases.

Young Offenders: An Enquiry Into Juvenile Delinquency. By A. M. Carr-Saunders, Hermann Mannheim and E. C. Rhodes. Cloth. Price, \$1.75. Pp. 168. New York: Macmillan Company; Cambridge: University Press, 1944.

This short book reports a survey beginning in 1938 and extending for a year, intended to disclose causes of crime in England as elicited by statistical means. There is a survey of previous studies, and the present analysis is made not only in London but in outlying communities, and a control group is added which is an unusual feature in statistical studies of delinquency. While there are many objections to the way the control group was selected, for each delinquent was matched with a boy of the same age who was not a delinquent from the same community, nevertheless the present study is unique and notes more strongly the influence of social factors emphasizing the beliefs that experts on delinquency have had for some years; for example, the importance of broken homes, the meaning of the presence of other delinquents in the family and the significance of leisure-time interests. There is no attempt to make a psychologic breakdown of the cases included, analyzing such factors as motives, mechanisms and diverse therapeutic procedures which in the United States are superseding this statistical approach to a great extent. Nevertheless the work has been soundly done and, while it has no bearing on delinquency in wartime, nevertheless it will probably form one of the statistical bricks in the edifice of delinquency prevention.

Fertility in Men: A Clinical Study of the Causes, Diagnosis, and Treatment of Impaired Fertility in Men. By Robert Sherman Hotchkiss, B.S., M.D., Lieutenant Commander (MC), U.S.N.R. With a foreword by Nicholson J. Eastman, M.D., Chairman, Editorial Committee, National Committee on Maternal Health. Fnbirkoid. Price, \$3.50. Pp. 216, with 95 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1944.

Fertility in Women: Causes, Diagnosis and Treatment of Impaired Fertility. By Samuel L. Siegel, M.D., F.A.C.S., Attending Obstetrician and Gynecologist, Brooklyn Women's Hospital. With a foreword by Robert Latou Dickinson, M.D. Fnbirkoid. Price, \$4.50. Pp. 450, with 194 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1944.

These companion volumes have been produced under the stimulus of a series of fortunate circumstances centering in the study of the fertility mechanism by a group of medical scientists and clinicians in New York City. The National Committee on Maternal Health and some of its officers share considerable responsibility with the two authors. The latter are men who have devoted much time to investigations in the fields about which they write, and consequently their evaluation of the work of other men is critical and also comprehensive. The books are well written, easy to read, liberally illustrated and thoroughly documented. The history of the subject occupies little space because of the relatively recent intensive and scientific studies of these fields. From the clinician's point of view these volumes will be helpful because they combine understanding of anatomy, physiology, pathology, bacteriology, endocrinology and clinical skill with therapy. They are not textbooks for beginners but will be unusually valuable handbooks for any clinician who expects to give thoughtful attention to the problems of fertility in either sex. Both authors stress the point that fertility must be considered as a bisexual problem and to a certain extent both partners of every marriage investigated before detailed studies of either one are attempted. Clinical and laboratory techniques described are presented with adequate details, so that any well trained clinician can use them without further laboratory guides or details.

The Principles and Practice of Ophthalmic Surgery. By Edmund B. Spaeth, M.D., Professor of Ophthalmology in the Graduate School of Medicine of the University of Pennsylvania, Philadelphia. Third edition. Cloth. Price, \$11. Pp. 934, with 562 illustrations. Philadelphia: Lea & Febiger, 1944.

The second edition of this excellent treatise on ophthalmic surgery was reviewed in these columns three years ago come November. The third edition, appearing after such a short time, reveals not so much the advances in surgery of the eye as it does the popular demand for a book of this caliber. It contains only 48 more pages than does its predecessor, but it has 105 valuable new illustrations. The most pronounced textual changes deal with the physiology of squint and with the development of nonsurgical principles associated with its correction. This is sound common sense writing, and the material is presented in a most understandable manner. The subject of ptosis has been revamped and reclassified, thus simplifying the principles of its surgical correction. The newest material in this edition is that dealing with gonioscopy, both preoperative and postoperative, with copious quotations from Kronfeld and Barkan. The chapter on the surgical treatment of detachment of the retina should be rewritten, eliminating some of the older operations that have been abandoned, such as the Guist, and elaborating somewhat more on the present day methods. A good working bibliography adds much to the usability of the book, which should be found on the work table of every operating ophthalmologist.

Hackh's Chemical Dictionary [American and British Usage] Containing the Words Generally Used in Chemistry, and Many of the Terms Used in the Related Sciences of Physics, Astrophysics, Mineralogy, Pharmacy, Agriculture, Biology, Medicine, Engineering, etc. Based on Recent Chemical Literature with Numerous Tables, Diagrams, Portraits and Other Illustrations. Third edition, by Julius Grant, M.Sc., Ph.D., F.R.I.C. Fnbirkoid. Price, \$12. Pp. 925, with illustrations. Philadelphia: Blakiston Company, 1944.

This chemical dictionary needs no introduction to chemists and those interested in allied subjects. Now in its third edition, the book should continue to serve as a good reference source for explanation of words frequently used in chemistry and other terms often found in physics, astrophysics, mineralogy, pharmacy, agriculture, biology, medicine, engineering and other sciences. More than fifty-seven thousand terms are defined. Theories, laws and rules, elements, compounds, drugs, minerals, apparatus, instruments and names of investigators are only part of the subject matter. In these days it is almost imperative for progressive physicians to be familiar with chemical terms; the present book will provide much help on this score when placed in the medical library. Unfortunately, some of the medical definitions, including those for digitalis, penicillin, calgon, pineal gland and phenobarbital, are not so clear or accurate as they might be, although this failing could be corrected in the next edition with the aid of a physician scientist.

Introduction to Physiological and Pathological Chemistry with Laboratory Experiments. By L. Earle Arnow, Ph.G., B.S., M.D., Director of Biochemical Research, Medical Research Division, Sharp & Dohme, Inc., Glenolden, Pennsylvania. With an Introduction by Katharine J. Densford, B.A., M.A., R.N., Director of the School of Nursing and Professor of Nursing, University of Minnesota, Minneapolis. Second edition. Cloth. Price, \$3.75. Pp. 574, with 144 illustrations. St. Louis: C. V. Mosby Company, 1943.

The second edition of this practical and well written book for nurses on physiologic and pathologic chemistry has been carefully revised. Newer data on sulfonamides, vitamins, the rennin mechanism of hypertension, hormones, muscle carbohydrate metabolism and other advances have been included. The first edition of the book was a contribution to nursing education in this field, and this edition ably perpetuates that distinction. Those who are not familiar with this textbook will find it one of the most effectively written volumes of its type. It is simply and authoritatively written and meets the current suggestions for teaching in this field by those interested in nursing education. Not only is the prevailing thought on biochemistry and physiology concisely presented, but the author's style is engaging. Those interested in nursing education will find this work authoritative and readable. It is highly recommended for nurses in training and for those who wish to keep abreast of current advances in physiology and chemistry.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CLIMATE IN ASTHMA

To the Editor:—The family of a 5 year old boy who is afflicted with an intractable case of chronic bronchitis and bronchial asthma has consulted me with a view to settling in one of the following localities for purposes of effecting a possible cure: El Paso, Texas; Reno, Nev.; Tucson, Ariz., and southern California. The youngster is allergic to house dust, dog and horse emanations, grass, plantain, ragweed, certain chemical compounds, as varnish, paint and lacquers, gasoline, kerosene, mustard, flaxseed, furnaces and gas stoves, and damp and musty places. Judging from available graphs relative to comparative climate, humidity and general atmospheric conditions, which of the cities mentioned (kindly cite a suitable southern California community of overage size population) would prove most beneficial? Which other localities not mentioned might be suggested for maximum end results? Also would the gaseous and chemical fumes generated by the mining smelters in El Paso prove detrimental?

M.D., Connecticut.

ANSWER:—In attempting to evolve a solution for the case in question it is important that one consider by what mechanisms an asthmatic person may expect to benefit as a result of a change in geographic location. The following are some of the explanations for the relief of asthma by a change of climate: 1. The removal of the patient from his allergenic environment may mean simply that a dog or cat or occupational source of allergy has been left behind. Or it may mean that the new general environment does not contain the same pollens, fungi or other atmospheric contaminants which were the cause of the patient's allergy. 2. In bacterial asthma, in asthma due to brouchitis or in cases in which the allergic asthma has become complicated by bronchitis, benefit may be obtained because of the favorable effect of some climates and regions on infectious respiratory processes. 3. Temperature changes, humidity and other physical atmospheric factors are known to affect asthma, both of allergic and intrinsic origin. As a simple illustration one may cite the ragweed sensitive patients who are most prone to precipitate their attacks of asthma after a sudden temperature change, fall in barometer or electrical storm. In certain regions such atmospheric contortions are at a minimum, so that some asthmatic patients are freed from one of the most potent causes precipitating their attacks. 4. An unclean air, due to soot, fumes and other chemical or mechanical irritants, may be an important factor. Some suburbanites may leave their home in apparent comfort and experience an attack of asthma when arriving in the city, particularly if atmospheric conditions have resulted in a low hanging, soot containing fog. Such patients may be benefited in rural districts, whether a few or several thousand miles away. 5. Psychogenic factors may also be at play in a climatic change. Benefit may be derived because of relaxation, being away from business or home environments and tensions, and because of the general psychic effect of a more pleasant climate. 6. Unexplainable influences may result in benefit to asthmatic patients not falling in the categories mentioned.

In applying these considerations to the case of the 5 year old boy it is quite evident that the information furnished is not entirely sufficient to justify an absolute opinion. It seems probable that three factors are at play in this case: allergy, bronchitis and influences of chemical irritants. If the pollen allergy is of major importance, southern California (Los Angeles, Pasadena, San Diego) should be satisfactory. If bronchitis is actually a prominent feature, Tucson would probably be the most desirable. If gasoline and similar chemical factors are largely to blame, the smaller communities in southern California or, perhaps, Tucson would be best. However, in such instances a home in a rural district in the patient's home state may also suffice. If weather changes seem to play a great part in the attacks, Tucson would be the best possibility. Attention should be called to the fact that, whether one can or cannot classify the patient in any of the groups mentioned, the individual's behavior is not entirely predictable. For a final opinion of the suitability of a chosen location or of even the desirability of any change, actual trial is the only answer.

No immediate information is available regarding the gases and fumes generated by the mining smelters in El Paso; if present in noticeable concentration, they would certainly be detrimental.

The reference of the inquirer to a "cure" is deserving of comment. Generally speaking, asthma due to allergy is not

cured by climatic change; it is only temporarily checked. The allergic irritation returns on the patient's return to his environment. Cure can be expected only in those cases in which the bronchial infection or inflammation has become the most important reason for the continuation of the asthma. In such instances the healing of the inflammatory process may condition the respiratory tract to be less susceptible to infection and perhaps also to allergy.

PLANTAR WARTS

To the Editor:—May I request information on the most effective treatment for the removal of plantar warts?

Captain, M. C., A. U. S.

ANSWER:—Plantar verruca is one of the most difficult dermatologic problems. Probably because of the thickness of the epidermis of the sole and the constant pressure on verrucae in this region, they are much harder to cure than in any other location. They are of the same nature and yield when curable to the same measures but less readily.

After the usual popular remedies, including suggestions have been tried and failed, the preferred treatment, painless, prompt and not apt to cause scars, is irradiation. MacKee (X-Rays and Radium in the Treatment of Disease of the Skin, ed. 3, Philadelphia, Lea & Febiger, 1938, p. 638) recommends small doses compared to those used by others, 300 roentgens for most cases, sometimes 450 to 600 roentgens. He warns against more than two doses, preferring to use electrodesiccation for further treatment. He insists on protection with lead foil to the very edge of the lesion and warns against use of the rays in inflamed warts or those that have had caustics used on them. In these cases wait for the irritative effect to subside before irradiating them. Allow at least a month after the last irradiation before using any irritating treatment.

Radium may be used, a half strength plaque with 1 mm. of aluminum, fifteen to thirty minutes or even longer. In thick hyperkeratotic lesions gamma radiation may be employed, using the half strength plaque with 1 mm. of brass and 1 mm. of aluminum for one to two hours or longer.

The use of electrosurgical modalities is perhaps the most popular of all methods of treating plantar warts and is effective in a good percentage of cases. It is difficult to use in young patients, however. One may use light applications repeated every week or two for a series of treatments.

CONTAMINATION OF FOOD WITH CIGARET ASH

To the Editor:—How harmful is cigaret tobacco ash, for example, when it is accidentally spilled on food and the food accidentally eaten?

M.D., Massachusetts.

ANSWER:—The ash of cigaret tobacco itself may contain traces of lead or arsenic, as well as carbon and mineral constituents, but in itself it is not harmful when ingested in small amounts. However, the incompletely burned cigaret tobacco behind the burning point may contain rather high concentrations of tobacco alkaloids, and so care should be taken to avoid contamination of food with material from the stump, behind the ash. Nicotine poisoning, with fatalities, has been reported from contamination of food with cigaret residues, but it is the unburned material, not the ash, which is here responsible.

LACERATED RECTUM FROM JOHNSON GRASS

To the Editor:—I want to report a case which, to me, is most unusual. A patient came in on July 10, 1944 complaining of severe lower abdominal pain. There was a rigidity of both sides at the lower abdomen. The abdomen was tender in this region, and there was a rebound tenderness also all over the whole lower part of the abdomen. He gave a history of having gone to a public toilet and, finding it occupied, he went into a nearby arched. He sat down quickly, and a stiff stem of Johnson grass entered the anus without producing visible injury to the anal opening. Because of the findings described and a white blood cell count of 22,000 within two hours after the injury, I opened the abdomen by means of a midline incision. On the anterior aspect of the rectum a lacerated longitudinal tear was found in the rectum about 1½ inches long. The lower part of the wound was just above the cul-de-sac. I closed the laceration with interrupted sutures of chromic catgut. The whole area was liberally sprinkled with 5 Gm. of sulfathiazole crystals. The abdomen was carefully wiped and the abdomen closed without drainage. The patient was put on a nonresidue diet and six days after operation was given a saline laxative. The wound healed by first intention except for the lower third, from which there was a small amount of subcutaneous drainage. He has made an uneventful recovery.

THE ROLE OF THE GENERAL PRACTITIONER

CHAIRMAN'S ADDRESS

J. CRAIG BOWMAN, M.D.
UPPER SANDUSKY, OHIO

Events on the home front in the last three years demonstrate more clearly than ever before that the general practitioner is still the central figure of American medicine.

COLLECTIVISM VS. AMERICANISM

We general practitioners, by virtue of our training, diagnostic services and analytical inclinations, are well equipped to help lead this country out of its economic and social maze. To do this best we must enter the lists first as citizens, and as doctors only when we can aid in the interpretation of the origin and the nature of the deteriorating social processes which are now plaguing this earth. We must come to the defense of those principles of government on which our fathers founded this nation. No other principles of government or system of medicine have ever succeeded so well. These principles, in recent years, have been challenged by those who would seek to give security against fear, want and sickness by taking from those who have and giving to those who have not. Those active in this movement fail to realize that these goals, which sound so attractive when they are defined by glittering generalities, can be obtained only through the redemption of man and never by the redistribution of what little real wealth is to be left in our land.

This strange ideology, entirely foreign to our country, is infiltrating itself into the muddled thinking of our people. We must recognize that, however attractive this sounds, social security demands that each citizen give up his individuality, his integrity, his intelligence and his independence in order that he may share in the redistribution of existing wealth. As biologists, we physicians know and must not hesitate to point out that nature has tried this pattern over and over again and has never produced anything more progressive than a colony of social insects—a heap of ants or a hive of bees. In terms of social progress, this biologic pathway has a blind ending. As physicians we must make our own patients see that social progress can come only as we emphasize the dignity of the common man, so that through variation in behavior this independence may here play its proper role in evolution.

HEALTH

The time has come for both the medical profession and the public to think more clearly about the relationship of the physician to the social order. Furthermore,

Read before the Section on Miscellaneous Topics, Sessions for the General Practitioner, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

it is important that the public begin to have a definite appreciation of both health and sickness.

Health is not negative. Health means more than simply keeping out of a physician's office. It is a positive condition of the body which gives us a long life of zest and buoyancy. Proponents of social insurance confuse, purposely no doubt, health with sickness and insist on labeling sickness insurance plans for indemnification in cash or in kind as health insurance, which they never are.

You and I, and every physician, have dedicated our lives to binding up the wounds and relieving the suffering of mankind. Advances in infant feeding and in immunization have made it possible to add a great many years to life expectancy in our time. These added years have brought upon us the added responsibility for the care of literally millions more who now suffer with degenerative diseases but who would have been dead long ago in another century. Likewise, as a result of this increase in life expectancy, we are confronted today with the ever increasing problem of the infirm aged. If society does not find a way to keep its old people healthy, alert and vigorous, the problem of their care threatens to break down completely the economic structure.

It is beginning to be appreciated that the chronically ill can only be repaired, never cured, even by the best of medical services. They cannot be restored to a truly healthy state. Modern science has done wonders in its attack on acute infectious diseases with serum and "miracle drugs." But those chronically ill with degenerative diseases can be treated only symptomatically and their lot made easier. This role of comforter, if it is to function at its best, involves the ideal physician-patient relationship.

MALNUTRITION THE CAUSE OF DISEASE

Medical research made one of its greatest contributions to human welfare when it began to produce positive evidence that improper or inadequate food, and a consequent state of poor nutrition, is the underlying cause of many diseases. Not only were organic diseases so identified, but poor nutrition was found to interfere with the proper working of the bodies of man and his animals.

Sickness produced by deficient foodstuffs was found, for the most part, to be chronic and crippling in character to both mind and body. We are coming to realize that chronic sickness due to faulty nutrition is the largest single factor in the lives of literally millions of the people who consult us but who do not, however, exhibit organic disease. They are simply poorly nourished and do not have their natural vitality. They have little or no vigor. They do have, as a consequence, an increased susceptibility to all kinds of infections and degenerative diseases. How to restore these chronically half-sick people to robust health before it is too late is a fundamental social problem.

This problem is not one of the redistribution of pills. It makes little difference who gives what colored pill to whom. What I am trying to say is that no plan of voluntary or compulsory sickness insurance will solve this problem. It is purely a matter of prevention through education, and sound nutrition and proper eating must become popular through education.

Let me illustrate what I mean by the studies which have been made on the Cincinnati Negroes. In the slum areas where the food supply, food preservation and food habits are all bad, they die like flies from rheumatic fever, tuberculosis and other diseases brought on by lowered resistance. In a Negro suburban village, under the average suburban standards of living, the relatives of these same Negroes die at the same rate and with the same diseases as do the white people of the neighboring town. Now one is particularly interested in the health problem of an individual colored citizen in these slums. Nutrition remains a personal matter. Once, however, his malnutrition has lowered his resistance and he is attacked by tuberculosis, then he is taken to a magnificent institution with marble halls. Doctors and nurses are provided in abundance to study his "case" and to serve him. Too often it is too late! The farm crops that we didn't raise and the milk that we didn't produce would have prevented him from ever getting tuberculosis in the first place. Prevention is the thing that is needed in meeting these problems, and the best preventive is good nutrition.

Or again—let me illustrate this point that much of the chronic half-sickness and of our disease is the result of malnutrition for which the medical profession cannot be blamed. Furthermore, any attempt to meet this situation on a nationwide scale with so-called adequate medical care will certainly bankrupt our economy. And the sad part of it is that there will be just as much sickness at the conclusion of the experiment as there was at the beginning. You will recall that during the depression the Dental Society of the State of Pennsylvania offered to fill free of charge the cavities in the teeth of all the children whose parents were on relief. This was, indeed, a noble gesture on the part of those dentists, and it cost them an immense amount in time, money, material and energy. The cavities, however, continued to develop faster than the dentists could fill them. This was because the children weren't getting enough foods rich in calcium and vitamin D. They were not getting milk and sunshine. It is therefore to be hoped that public attention will not become fixed on some scheme for getting sick people to a physician, but rather that the public will realize that these undernourished people are sick and always will be sick with one disease or another as long as they live, unless their nutrition can be restored. Prevention, I must insist, is needed, and this is a task for all of Society and not a task for physicians alone.

OUR PATIENTS

Those of us who are engaged in general practice realize, as many other people do not, that some of the basic relationships which governed the art of healing, before the separation of medicine from religion, are still needed in the handling of sick patients. At least one half of the patients seen in the office of the general practitioner do not have the typical diseases that are described in our textbooks on the practice of medicine. They are, on the contrary, victims of functional disturbances and frustrations, which have come primarily from bad adjustments to environment, and are increas-

ingly common in these days of perplexing social and economic stress.

These half sick patients demand something more than the right of the individual to select his own physician. They must, however, have this right and exercise it if they are to have confidence in their adviser. Such patients must develop a relationship which will inspire in them confidence in the judgment and advice of their own personal physician.

This is a challenge which we readily accept. In so doing we utilize our art and skill in such a manner as to bring the patient quickly to a realization that the doctor whom he has chosen as his physician and counselor has had intimate experiences in directing the lives of others and in helping them to sublimate their frustrations and to adjust themselves more satisfactorily to all the other problems which arise in life. To meet this challenge the general practitioner must continue to be more than a scientist—he must still be teacher, philosopher, counselor—friend.

PERSONAL PREVENTIVE MEDICINE

When one attempts to look into the future, it is difficult to see the end of present social trends. It is certain, however, that the practice of personal preventive medicine will become increasingly important. It will place greater responsibility on the shoulders of the physician in general practice. No health department or any other agency, regardless of how well it is manned or financed, can handle this completely. The host of procedures—immunization, vaccinations, examinations and analyses—that the alert citizen is supposed to have done for him even now is beyond the resources that are conceivable for any public health department. This requires a complete and mutual understanding and cooperation of the family physician and his families and opens a great field in personal preventive medicine. The public will be fully appreciative in every sense of these services if it is allowed to cooperate and understand.

SERVICE FOR THE RETURNING SOLDIER

Following the war—even before it ends—the medical profession will be confronted with the vital task of helping the millions of men returning from the service to readjust themselves to civilian life and to help restore them to physical and mental fitness. No one is so well fitted to help these men to make the necessary mental readjustments as the general practitioner.

After the war we shall need to have a knowledge of many strange diseases which the boys will bring back with them from many foreign shores. Many ex-service men will become institutionalized unnecessarily unless each one of us prepares himself to render the kind of service which these men will need and will want. The unusual mental impairments of sickness will make it imperative that these men get counsel and advice from some one on whose judgment they will rely and who is competent to analyze them as whole human beings, not simply as battle casualties—and a beautiful specimen for a case report. Psychosomatic medicine is a new name for this use of sound judgment and intelligent understanding of life that has always characterized the work of a good general practitioner.

CONCLUSION

Today we stand on the threshold of a new era in medicine—an era which offers a great challenge to any one in general practice. If the physician will continue to develop his relationship with his families along the

lines that I have tried to suggest in a general way, he will continue to render a distinct service to a large portion of our people. At the same time he will make a definite contribution toward molding the pattern of the future practice of the art and science of healing.

208 South Sandusky Avenue.

STANOCOLA MEDICAL CARE PLAN

JAMES M. ADAMS, M.D.

NEW YORK

The features of the Stanocola Medical and Hospital Association are as follows:

1. It was conceived and organized and is owned, supported and operated by employees.
2. Membership is entirely voluntary.
3. It supplies necessary medical, hospital and nursing services to employee members and to their families.
4. There is only one rate of dues, regardless of the number of dependents.
5. The medical staff is on salary and mainly on full time.

Although it is employee owned and operated, the company is much interested in its success and lends its support by:

1. Making payroll deduction of dues.
2. Permitting deduction of dues from the company thrift fund. This fund is supported by regular, voluntary contributions by employees and by the company. Dues collected from this fund, as 85 per cent of them are, represent both employee and company contributions. Through the medium of this fund, members of the association thus receive material help from the company in the payment of their dues.
3. The company has aided the association substantially by making a large donation toward the purchase of its clinic building and on other occasions made contributions for special purposes.
4. The board of directors of the association has always included two or more of the company's executives, elected by the membership.

The association is entirely distinct from the company's medical department, whose work is limited to industrial medicine—preventive medicine and the care of industrial injuries and diseases. It was organized and the collection of dues begun on April 1, 1924, and services were offered beginning July 1 of that year, so that it has now operated successfully for twenty years.

In the early 1920s the employees of the Standard Oil Company of Louisiana in Baton Rouge had suffered a reduction in income. At a general conference of representatives of the employees and the management, opinions were expressed by employee representatives that the cost of living in the city, which at that time was largely a single industry town, had not been reduced commensurately with that of the country as a whole or with their loss in income. Committees of employees were created to consult with various business and professional groups in the city seeking a reduction in prices and fees. Among these committees was one to consult with the medical society looking toward a return to the schedule of fees customarily charged prior to the war.

This committee was unsuccessful in its mission, and after many discussions an association was launched with the object of securing a reduction in medical costs.

This was composed of 1,300 employees, who made an agreement with four physicians in the community to pay them a retainer of one dollar a year for each member. The four physicians divided this fund and agreed to treat the members and their families at one half the usual fees.

As was to be expected, this arrangement was unsatisfactory both to the members and to the physicians and the arrangement was not renewed after one year. The experiment served, however, as a basis for the promotion of the Stanocola Medical and Hospital Association.

At that time there were few organizations attempting to supply group medical service and no precedents to guide the founders, so that the project had to be inaugurated on a strictly experimental basis. There were then no Blue Cross Hospital plans, and in that area about the only group medical care was supplied by lumber companies to their employees, usually in isolated camps. Deductions from wages were compulsory and a doctor or doctors were employed by the companies to care for the medical needs of the employees and their families. In many instances the revenues from the collections were much greater than the expenses, and the companies were in effect practicing medicine for profit. Only the largest companies supplied hospitalization and then in hospitals of their own. The service was often inadequate and inefficient.

It was decided that 2,000 members would be a minimum for beginning operations, and after a thorough canvass of the refinery personnel the experiment was launched with 2,200 employees and their families participating. Arrangements were made with several private practitioners to treat the eligible beneficiaries, utilizing their own offices. Included in the panel were a surgeon, who served as medical director, and an ear, nose and throat specialist. After about six months of operation a group of offices for a clinic was rented and all physicians except the surgeon were placed on full time. Three years later the surgeon and medical director was employed on full time.

In 1931 the group, having outgrown its quarters, purchased a large residence in a convenient location and converted it into a clinic, which is still in use. The staff now consists of eleven doctors on full time and five on part time. Of the physicians on full time two are surgeons, one of them serving as medical director, a pediatrician, an ear, nose and throat specialist, an obstetrician and gynecologist, five general practitioners and one of the older physicians, who confines his work to anesthesia and office practice. One of the general practitioners, who also is one of the older men, is located in a nearby town and cares for the members residing in that immediate community. Of the part time physicians one is a roentgenologist, two are general practitioners in nearby towns and the other two are used for relief work in the pediatric service. Two of the physicians are women.

In addition to the medical staff, six nurses (two graduates and four nongraduates), two laboratory technicians, an x-ray technician, two office girls and a cleaning staff are employed in the clinic, and a couple living in the garage look after telephone calls when the offices are closed. Hours at the clinic are from 8:30 a. m. to 6 p. m.

The character and training of the medical staff are excellent. All physicians are graduates of approved medical schools and most of them have had postgraduate training. All are members of the American Medical

Read in a panel discussion on "Variations in Industrial Medical Service Plans" before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

Association and two are fellows of the American College of Surgeons.

There are seven suites of offices, most of them used by two physicians at different periods, and their hours are staggered so that there are always several on duty throughout the day. Each doctor has one day off each week. There are clinical and x-ray laboratories, physical therapy treatment rooms, and a pharmacy operated by a drug store chain which fills prescriptions at a 15 to 25 per cent discount. New x-ray equipment has just been installed, which includes in addition to the regular x-ray machine a fluoroscope and a wall dental unit.

Aid provided starts with medical and surgical services limited only by the capacity of the staff. Patients are treated in the clinic, in the hospitals or in their homes within a radius of 7 miles of the clinic, as indicated. Beyond the 7 mile limit a small mileage fee is paid by the patient to the doctor. Hospitalization is at ward rates except that private rooms are provided for contagious diseases and where privacy is a necessary part of the treatment. The general hospitals in Baton Rouge are used and accord special rates to the association. Special nurses are provided where they are considered necessary. Hospitalization and nursing costs are limited to \$250 for each case. For those members who call a physician who is not on the association's staff, hospitalization and special nurses may be supplied up to the maximum at the discretion of the medical director. Hospitalization of normal maternity cases is not provided. However, on the advice of the association's obstetrician, practically all normal obstetric cases go to a hospital for delivery, with hospitalization costs at the patient's expense. Hospitalization and special nursing have recently been authorized outside the Baton Rouge area. Medicines other than those administered in the clinic are not supplied. Services are the same for employees and for their dependent families. Dependents eligible to services are limited to parents, spouse and children. Other dependent relatives may be included by the payment of additional monthly dues.

Dues were set in the beginning at \$2 per month for each member. No distinction is made in dues for members with dependents from those who have none. The board of directors was authorized to make up to one assessment equaling a month's dues in each quarter. As it was found necessary to make a number of assessments regularly, dues were increased and are now set at \$3 a month, with three assessments of \$3 permitted during any one year. On an average two assessments are now being made annually, bringing the cost to \$42 per member year or \$3.50 per member month. It has been suggested that the dues should vary with the number of dependents and possibly with the income of the members. But the organizers wanted a fully cooperative association and considered the single rate to be as equitable as single rate group insurance premiums. It has also been suggested that the dues be increased to \$3.50 per month, as that is the actual present cost. But the board of directors regards the present plan of dues with assessments made only as required as preferable. The x-ray department is supported separately from the other services, and assessments are made as needed for its maintenance. One assessment annually, included in the two mentioned, is usually sufficient. For employees who wish to enroll dependents other than parents, spouse or children, one dollar a month is charged for each such dependent.

In 1930 the association was incorporated as a non-profit organization with capitalization at \$100,000, represented by five thousand shares of stock at \$20 each, every member being required to purchase one share of stock which may be paid for at the rate of \$1 per month. These funds are for use for capital investments, improvements and new equipment. The stock carries no voting power and is of value only in the event of liquidation. All stock has now been subscribed, and an initiation fee of \$20 is substituted and required of each new member.

The business management of the association is vested in a board of directors consisting of eleven members elected by popular vote for overlapping terms of two years. Eight are elected from specified groups of departments and the remaining three from the membership at large. Ever since the organization of the association, two or more members of the board of directors have been executives of the company elected by the membership at large. The professional direction of the staff is in the hands of the medical director and there is no interference from the board in any professional matters. The cooperation between the board as business managers and the chief surgeon as professional director has always been excellent.

Disbursement of Revenues

	Percentage of Revenues	Monthly Cost per Member	Monthly Cost per Beneficiary
Doctors' salaries.....	40%	\$1.40	\$0.26
Hospitalization.....	20%	0.70	0.18
Special nurses.....	10%	0.35	0.09
X-ray department.....	6%	0.21	0.06
General and administrative expense.....	18%	0.63	0.16
Other expense.....	5%	0.17	0.04
To surplus.....	1%	0.04	0.01
Total.....	100%	\$3.50	\$0.20

The expansion of services has been slow and careful. New ventures have been embarked on only after long and serious study. For example, when the x-ray department was inaugurated it was as an extra service and was supported by charges against the patients for x-ray examinations. As this plan was contrary to the strictly cooperative spirit of the association, it was decided by the membership to support it by assessments as required against all members and to make the service available without additional cost to those needing it.

During most of the period of its existence its membership has comprised 80 to 90 per cent of the eligible employees. It now numbers 4,600 members, with 18,000 persons eligible to services. The rapid increase in employment at the plant during the war period has posed a problem. Additions to and replacement of the medical staff have been almost impossible to secure because of the doctor shortage. In order to avoid contracting for more services than their available facilities will permit, new memberships are being restricted to employees with a year or more of service, and the regular staff has been supplemented by the part time employment of local private physicians.

The association now has assets amounting to \$140,000, represented by real estate, equipment, war bonds and cash. It has been suggested that an organization with an annual budget of almost \$200,000 should have a larger reserve for epidemics and catastrophes. Actually the amount of service rendered is strictly limited by the facilities available in the community and little more can be provided, regardless of the needs, than is now

being supplied. While the number of members has increased one third in the past two or three years, the increase in the amount of services rendered has been much smaller. In fact, special nursing services supplied were actually less in 1943 than in preceding years, simply because there were often no nurses available when needed. The flexibility of income resulting from the authority to collect assessments cares for normal fluctuations in costs, so that the financial structure seems adequate.

During the seven years 1936 to 1942 the revenues have been disbursed in average proportions shown in the accompanying table.

ADVANTAGES TO MEMBERS.

1. The members of the association have adequate medical hospital and nursing care for themselves and for their families at a predetermined cost. The total cost is probably as great as if the group purchased the service individually; but they have probably received more service than they would have purchased as individuals.

2. They have been supplied with services at least the equal in quality of that otherwise available, and superior to that usually received by persons in the same economic group. They have had the advantage of much freer consultation with specialists than they would have had otherwise, and laboratory and x-ray examinations are more freely used.

3. They have escaped a not infrequent cause for strangling debt—large medical and hospital bills.

4. They have the satisfaction of providing this care for themselves and their families by their own efforts rather than having it handed to them.

ADVANTAGES TO THE EMPLOYER

1. Adequate medical care for the employee is provided, with return to duty with the minimum loss of time.

2. Close cooperation exists between the company's medical department and the employee's physician.

3. It is easier to persuade employees to have physical defects corrected than it would be otherwise.

4. Fraudulent claims of industrial injury are reduced.

5. The morale of the employees is improved by freedom from worry over costs of illness and by the satisfaction of providing such excellent medical care through their own efforts.

ADVANTAGES TO THE MEDICAL STAFF OF THE ASSOCIATION

1. The compensation is probably higher than the average in the community in normal times.

2. The inconvenience of carrying on an individual business is avoided.

3. Each physician has one day off each week and an annual vacation with pay.

4. Postgraduate training at the expense of the association is provided on occasions.

5. The close association and consultation with other physicians stimulates them to better work.

CONCLUSION

In 1932 a study of the association was made by Dr. Rufus Rorem of the Blue Cross Hospitalization program of the American Hospital Association, at that time representing the Julius Rosenwald Fund, and Dr. John H. Musser, professor of medicine at Tulane University and past president of the American College

of Physicians. Their report was published in book form under the title "Group Payment for Medical Care" and approved the work of the association. Dr. Musser commented on the maintenance of the personal relationship of the physician and the patient. Free choice among the general practitioners is permitted, and the physician stands in the same relation to the patient as the "family doctor."

The association members, the management of the company, the company's medical department and the medical staff of the association are convinced of the value of the organization for this particular group. It is equally recognized that it is not necessarily the ideal plan for all groups.

Standard Oil Company (New Jersey), 30 Rockefeller Plaza.

VARIATIONS IN CURRENT INDUSTRIAL MEDICAL SERVICE PLANS

M. S. BLOOM, M.D.

BINGHAMTON, N. Y.

Industrial medicine is probably more widely practiced in the Binghamton area than in any other part of the country. For a number of years I have been medical adviser for several concerns in Binghamton and surrounding cities. While I have been associated with industrial medicine, I have also continued to maintain a private practice. This has enabled me to understand both sides of a subject which has made significant development in recent years.

At present I am medical director in six industrial organizations with a total of over 5,000 employees and about 2,000 dependents participating in prepayment medical care. I shall try to present a few of the details concerning some of the plans under my direction.

In 1913 a Mutual Benefit Association was organized at the Dunn and McCarthy shoe factory by the employees. Sickness and death benefits were provided. Later a registered nurse was hired and a complete and well equipped first aid room was established. In 1916 I was employed as the company doctor to conduct a clinic every morning and to visit sick employees at their homes. There were 1,200 employees at the time. The company contributed 50 cents for every dollar contributed by the workers. In 1923 the firm started contributing dollar for dollar, and new services were added. This association gradually expanded until we now have a fairly complete coverage of the medical, hospital and dental needs of the members. In 1928 care for dependents was instituted. The benefits for dependents include major and minor operations, hospitalization at ward rates, laboratory and x-ray service and care of fractures. There is a limit of \$250 to be spent per contributor annually for his dependents.

In paying for and drawing sick benefits, members are divided into classes according to their weekly earnings. Dues are 15, 20 and 25 cents a week, and 10 cents additional for care of dependents. We feel that this method of contribution is most satisfactory because those in the lower income groups have an equal opportunity to share benefits with those in the higher income levels. It also affords those paying greater contributions sick benefits in proportion to their dues.

Read in a panel discussion on "Variations in Industrial Medical Service Plans" before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944

Any employee may join the association, but he must pay dues for two months before he is entitled to benefits, six months to be eligible for hospitalization and operation, eye examinations, x-ray and extraction of teeth, and one year before receiving sick benefits when he is operated on. No member can draw more than ten weeks' sick benefits in a year, and not more than \$350 can be spent on any member in a year. This is a limitation placed by state law.

At Dunn and McCarthy's the twenty-two year average cost per employee was \$18.53 annually; the sixteen year average cost per contributor for his dependents was \$13.43; the cost per dependent was \$5.17 a year. These figures are significant because they furnished a basis for the organization of other mutual benefit associations in other industries. There are many ramifications to the Dunn and McCarthy plan which I have not time to go into here. It is based primarily on the contract method of practice. The workers are allowed to choose their surgeons, specialists and dentists.

In 1930 a benefit association was organized at the Spaulding Bakeries plant in Binghamton. This plan was later extended to the other Spaulding plants in New York State and Pennsylvania. Originally this association was organized on a contract basis. After two years the question arose as to whether it would be possible or feasible to allow the employees the freedom of choice in the selection of their physicians. It was found that, although some of the members paid dues in the association, they continued to go to their own physicians. The officers of the association sensed a tremendous advantage in the personal relationship which exists between a physician and his patient and the desirability of maintaining that relationship through the association. It was decided to try giving the members the right to choose their physicians. We were pioneering and had no assurance what the outcome would be. The reorganization of the association under the new principle succeeded beyond our hopes. It was proved that the principle of freedom of choice was the ideal setup. The doctor himself now had a stake in the success of the plan, and the patient knew the limitations. The doctor knew that he would get paid for the services he rendered and he knew there were limits to what the association could afford to pay. We believe, after considerable research, that the Spaulding Employees' Mutual Benefit Association was the first to establish the fact that complete freedom of choice was workable and effective.

The average annual cost per member in the Binghamton plant for eleven years was \$26.77, for nine years in the Elmira plant \$24.73, for eight years in the Oneonta plant \$14.94, for eight years in the Wilkes-Barre plant \$14.93, and for seven years in the Middletown plant \$19.30. The average annual cost per member in the five plants was \$20.13.

In the Binghamton plant we have limited care of dependents. This care includes house and office calls, x-rays and laboratory fees. The average annual cost per contributor was \$19, and \$9.40 per dependent. There is a limit of \$50 a year to be spent in any year per contributor for his dependents. Dues are 25 cents a week per contributor.

The success of the association at Spaulding's led to the organization in other local industries of other associations based on the same general form. In some instances it was the result of employees asking their employers for a plan for prepayment medical care.

Probably the most convincing evidence of the value of medical departments in industry is the fact that where these departments have been established they continue to exist and to increase in usefulness. Employers and employees soon realize the advantages.

In 1929 the Ansco Corporation organized a mutual benefit association, which operated for four years on a contract basis. The success of the Spaulding Plan under freedom of choice led us to adopt the same principle at Ansco in 1933. The company contributed 50 cents for every dollar contributed by the employees.

In February of 1943, because of increased costs of hospitalization, dues had to be raised from \$1 a month to \$1.25. The company agreed to contribute 75 cents a month for each member. With the increase in dues, x-ray and extraction of teeth were added to the benefits and \$4 a day was allowed for hospitalization instead of the \$3 originally allowed. We found that, with the added income, expenses were less than anticipated, so on Nov. 1, 1943 we increased the allowance for x-ray and laboratory and gave sick relief when the patient was operated on or hospitalized. The total allowance to be spent per employee annually was increased from \$250 to \$300.

Ozolid Products Division was incorporated into the Ansco Association in 1941. Benefits in these associations now include major operations with an allowance of \$100, minor operations up to \$50, tonsil operations \$40, hospital, with a thirty day limit, \$4 a day, anesthetic \$5 to \$15, operating room fee \$5 to \$20, ambulance \$6, laboratory \$20 a year, electrocardiographs \$30 a year, consultations \$10 a year, x-rays \$40 a year, surgical office calls \$50 a year, refractions \$5 a year, x-ray and extraction of teeth \$25 a year, \$3 allowance for house visits and \$2 for office visits with a limit of \$30 to be spent annually. For oxygen and transfusions there is an unlimited allowance. Benefits of \$10.50 a week or \$1.50 a day are paid after seven days of illness for not more than seventy days a year; after seven days' hospitalization for not more than thirty-five days. There are over 3,000 members participating in the Ansco Mutual Benefit Association. The average annual cost per member for an eleven year period was \$18.25.

In March 1944 we added care for dependents at Ansco. The dues are \$1.50 a month. Wives and dependent children under 18 years of age are entitled to major and minor operations, hospitalization for thirty days a year at \$2 a day, care of fractures and maternity care. We placed a limit of \$40 for doctor's fees for maternity care, plus the allowance for hospitalization. Dependents of members who enter the armed forces will be eligible for benefits, provided the monthly dues are paid.

During 1943 the Ansco Mutual Benefit Association paid 147 doctors in sixty-seven different cities and fifteen different states. This was in addition to the 102 doctors used in the city. Hospitalization was provided in twelve different hospitals and the employees used 33 dentists out of town and 23 in town.

Our policy has always been to extend benefits rather than to reduce contributions as funds accumulated. In all the associations the members are asked whether they wished to contribute additional amounts for additional services. In all cases of extension of benefits and additions to dues the members have voted for it by a large majority.

The smallest mutual benefit association is at the Binghamton Die and Machine Company, where there are less than fifty employees. This association has been

operating successfully since Jan. 1, 1937. Coverage is practically the same as in the larger associations. The average annual cost per member for the seven year period was \$17.97.

The newest association is at the H & A Manufacturing Company. This went into effect on May 1. It is different from the other associations in that the employer is paying the entire cost.

The expenditures in each association vary but little. These variations are determined by the length of time the association has been in operation, the number of employees and the size of the contributions of the employer and employee.

The real measure of any plan is not its good intention but its actual achievement. The associations in which freedom of choice is practiced are working with amazing success. We have developed a plan that is equally acceptable to physician and patient. Members can select from the outstanding physicians in the community. We know that individual attention by a skilled and interested physician is the best type of medical care.

Our experience indicates that with proper administration and with cooperation between the associations and the medical societies this type of service to the worker can be provided in industry on the basis of complete freedom of choice of physicians. It is evident that from small beginnings the mutual benefit associations grow rapidly to provide a more varied and more complete medical coverage.

One great advantage in our plan is that it can readily be adapted to every kind of industry, with the costs set at a point where the plan may operate successfully.

It has been thoroughly established that the people are interested in prepaying their medical costs. The costs of medical care should be distributed among groups of people and over periods of time. Americans cherish the right to exercise their free will and judgment. There must always be this right if American medicine is to advance in the future as it has in the past.

Freedom of choice of physicians is to be preferred to the contract or panel method. The patient receives attention without delay because all physicians in the community are available. Illness comes under skilled observation and much sooner than would be the case otherwise. Clinical methods are more widely used, and accurate diagnosis is more readily established. X-ray, laboratory and specialized services are available to those who otherwise could not afford them.

Under freedom of choice, the principles on which the practice of medicine were established have remained intact. There is better relationship between doctor and patient, a greater degree of cooperation in the medical profession and a greater feeling of good will between employer and employee.

Many attempts have been made to give adequate and efficient medical service and to make it easier for those of modest means to pay for this service. We physicians are sympathetic with efforts to improve conditions and deeply concerned with any attempt to change the fundamental basis of our work, but we must realize that, with the advances in medical science, other advances are being made. The maintenance of a strong medical profession is in the public interest. We must increase our efforts, because the physician has no more important obligation today than to assume a place of leadership in solving the economic and social problems bound up in the practice of medicine. The economic organization of medical care is now undergoing changes of great scope and magnitude. These changes are partly

because of the growth of public sentiment that health is a matter of social concern. Change based on anything but sound practices can result only in eventual detriment to the medical profession and the people.

My close association with industrial workers over a period of years has convinced me that they favor prepayment in order to free themselves of the worry of medical care. While industrialists have been willing to assume their part in the program of medical care, medical societies have been reluctant. These societies can efficiently handle the whole program. The medical profession will gain nothing and make no progress by working at cross purposes with the trend of the times or with the desires of the people. We must take an interest in medical economics and, through our medical societies, furnish the leadership necessary to make prepayment available to every one who wishes to participate.

110 Oak Street.

HEALTH PLAN PRINCIPLES IN THE KAISER INDUSTRIES

SIDNEY R. GARFIELD, M.D.

OAKLAND, CALIF.

We have a fundamental concept. Though there are certain hazards and occupational diseases peculiar to industry, these are rapidly being eliminated and are actually minor problems superimposed on the general health problem of the worker and his family. Industrial health actually resolves itself to be not an entity but the basic health of the American people.

American medicine surpasses that of the rest of the world in technical excellence. So far a large portion of the American people have been denied this medical care. This lack of distribution has led to numerous experiments to solve the problem. During the last ten years some three hundred medical care plans have developed. This is a significant trend of vital concern to the medical profession. Most of these plans have one common characteristic—"prepayment." From there on they deviate widely in amount of coverage, financial structure, organization and ideals.

Groups of experts have developed—so-called authorities—who are found in government agencies, foundations and labor unions, among employers, insurance companies and public health schools. Most groups are trending toward a united front, completely bypassing the medical profession—the trend toward government tax supported medicine.

Now there appears to be a definite drive to forestall the threat of government intervention by medical society operated prepayment plans. The facts are that prepayment itself is not enough. The majority of prepaid medical plans to date have failed and proved totally inadequate:

(a) The insurance company indemnity plans provide only a minimum of service.

(b) The Blue Cross plans have only limited hospital care and in addition have a possibility of dominating the medical profession.

(c) The medical society plans have been miserable failures. Starting with comprehensive coverage, they have dropped back to limited benefits; they have not

Read in a panel discussion on "Variations in Industrial Medical Service Plans" before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

been supported by the physicians; they have created no facilities, have not raised the quality of medical care and are too expensive and do not provide for preventive medicine.

In short, in addition to prepayment there must be some semblance of organization in methods of providing medical and hospital care so that the prepaid funds will provide the necessary coverage and sufficiently remunerate the physician.

Ten years ago we started providing medical care with no preconceived ideas and no plan. We had industrial work to do in areas where no medical or hospital care existed. We tried the usual method of fee for service and soon discarded it. We could not provide the service on that basis and the people could not pay for it. Out of our necessity evolved a simple plan that works. We have tested it under all sorts of conditions and in many areas with small numbers of men and large numbers—with scattered groups and concentrated groups. I would like to present this plan for your consideration.

The plan embodies three major principles: (1) prepayment, (2) group practice and (3) adequate facilities.

Prepayment needs no elaboration and is generally accepted as the only way people of moderate means can pay for increasing costs of modern medical care—the principle of spreading the cost so that the well pay for the sick.

Group practice, the second principle, results in many economies, the most important economy resulting from the highest quality of medical care for each illness. Most highly developed in the very universities that teach us medicine, few will deny the advantages of group practice, its stimulation to the physician, its ready accessibility for consultation, its better supervision and utilization of the younger and inexperienced physician, its productiveness in research and training. In fact, most physicians today have an unofficial association with a group of doctors; but these groups are totally unorganized, inefficient and costly.

Adequate facilities, the third principle, are equally important. By adequate facilities I mean bringing the doctor's offices, the hospital, the laboratory and x-rays together under one roof. Where such facilities are geared to serve one particular group we achieve the utmost in efficiency and economy and the greatest accessibility between doctor, patient and workshop, with a resulting tremendous economy in saving of travel and duplication of equipment and personnel. That in essence is the plan. Consider these facts: Utilizing these principles in just a period of twenty months we have served the medical needs of 80,000 people in the Oakland area. Our income has been prewar income, the same cost to the worker and the employer that we charged five years ago. Contrary to what you may have read, the people we serve are not a selected group; they are the 4F's, the aged and the physically unfit. Many would be considered unemployable in normal times. Incidentally these men have done an outstanding job in shipbuilding. We have no preemployment examinations. The unions will not permit that—a rebound from the old days when such examinations were used to keep men from working rather than for proper placement. As a result we have had a tremendous medical load. We have provided these men with more medical and hospital care than has ever before been provided a similar group of people. Despite these facts, the tremendous medical load and wartime increases in expenses, we have been able to remunerate

our physicians with incomes ranging from \$5,000 to \$15,000 a year net. We have been able to build and pay for close to one million dollars worth of facilities and equipment and in addition have provided about \$50,000 for training and research, all by the utilization of prepayment-group practice and adequate facilities.

You have heard and read many things about our organization. I can honestly say that the only thing wrong with what we are doing is that neither Mr. Kaiser nor I should be doing it. The doctors through their medical organizations should be doing the job. If they would, they could raise American medicine far beyond its present level, superlative as it is, and, what is more important, bring it to the people.

Those three principles prepayment, group practice and adequate facilities are the solution to medical care. There isn't a question or problem in medicine they can't answer. In effect it means organization of medical care, which has been delayed too long. It would preserve individual enterprise in medicine. Medicine has developed to the point of specialization where the individual physician can no longer be a separate enterprise. The individual group, however, can be. The free choice of the future will be the free choice of a group. There is a tendency to be conservative and move slowly in such matters, but it would be wise in this problem to take bold steps. Group practice needs no experimentation. It has proved itself in the clinics and universities of this country.

The job could be done on the basis of the state medical society and could cover all areas of the state, country and city with one statewide service. The doctors of the state could voluntarily align themselves into three groups: (1) those desiring to work in full time group practice on a budgeted yearly income, (2) those desiring to work part time with these groups at a salary and retain some private practice and (3) those desiring to remain in private practice. Those choosing full time group work would probably be the younger men and many of those returning from the armed services. Those choosing part time group work would be the middle of the road physicians who would not want to give up the private practice they had built up and would on the other hand wish to have some contact with the group. Those choosing to remain in private practice solely would probably be the older men with large lucrative practices who chiefly serve the well-to-do classes. These men could serve as consultants and teachers for the full time group on a fee basis.

So all physicians could align themselves in these classes. From those volunteering for full time group work a board of highly trained physicians could select ideal groups or as nearly ideal as possible and back them up with part time physicians. With careful planning the medical centers could be built in strategic areas, city and country, serving 50 to 60 thousand people each, these centers being staffed with the groups selected. Radiating from each medical center would be the diagnostic and treatment centers, bringing readily accessible care, preventive and curative, to the outlying areas.

Such a reorganization of medicine sponsored by the medical societies has unlimited possibilities. Neither government, industry nor anybody else could touch it. Under such an arrangement medical care could easily be paid for and therefore reach all the people. There would be an increase in net income to the physicians; they would live a decent life with time off for vacations and study and home life without worrying about losing

their practices. There would be a redistribution of medical care so that the country areas would be better supplied with facilities and specialties—a new hospital financial structure which would stand on its own feet and be controlled by the physicians. The younger physician coming out of training could be assured of an immediate good income and be utilized to the maximum of his capacity under supervision and there would be a great stimulus to research and training. And very important is the fact that medical care would remain in the hands of the physician, where it belongs.

One last word: Under such an arrangement the physician and hospital are better off if the patient never gets sick. With the modern discoveries in medicine and those yet to come, the medical care of the sick is a diminishing economy. Would it not be wiser to create now a new economy of medicine, remunerating the physician for keeping the patient well?

ENDICOTT-JOHNSON MEDICAL PLAN

EDWARD M. JONES, M.D.

ENDICOTT, N. Y.

The Endicott-Johnson corporation is engaged in the business of tanning leather and manufacturing shoes. Their factories are located along the southern border of New York State about midway between Buffalo and New York City. The principal factories are located in Johnson City and Endicott, villages of about 25,000 people each. Smaller factories are located in Binghamton and Owego. These communities are all geographically closely related, starting on the east with Binghamton, whose western boundary merges with that of Johnson City, and continuing on to Endicott, which is located about 5 miles west of Johnson City. Owego is about 18 miles west of Endicott.

In 1918 Mr. George F. Johnson, the founder of the company, decided to give to his workers a complete medical service, not only for themselves, but also for the dependent members of their families. He was prompted to do this as a part of a broad program to improve the living conditions of the workers and their families and to help them keep out of debt. He was firmly convinced that debt was a great factor in the unhappiness of the average worker and that, many times, unexpected large medical bills were the cause of this. He felt that relieving the worker of the cost of his own medical care alone was not sufficient and therefore included all those for whom the worker might reasonably be expected to assume financial responsibility in case of sickness. Although, during the years that have followed, the boundaries of this liability have varied somewhat, nevertheless that has been the general principle which has governed the extension of service to the dependents of workers.

There has never been any attempt to make this service a research institution. We have not tried to develop it as a model for other corporations. It has been an attempt to give the workers complete medical care of high quality with reasonable freedom of choice of physician, hospitalization, medicines, laboratory and x-ray examinations without any limitation except for the necessity of the case.

The expense of this service, which has varied from around \$700,000 to \$1,000,000 a year, has been assumed entirely by the company as an operating cost, except for the period from April 1931 to September 1933, when the cost was met by a 5 per cent payroll deduction. When business conditions improved, however, the company not only reassumed the cost of the medical department but, in addition, returned to each worker the total amount that had been taken out of the pay checks during the period of the 5 per cent deduction.

The number of workers eligible for service has varied somewhat during the ensuing twenty-six years but has averaged around 17,000. The average number of dependents has been around 32,000, or a little less than 2 dependents for each worker. At first all workers were included in the service from the day of their employment, but because of the abuse of this system whereby individuals could work for the company for a few days and then apply for medical care for some condition which had been in existence for considerable time and which might require prolonged hospitalization and major surgery for its correction, this was changed so that medical service was not extended to a new worker until after a probationary period of six months. In September 1940, when the accelerated defense program began to get under way, the company began to hire a great number of temporary workers. At that time it was felt that these workers would be on the payroll only temporarily, and if there was a falling off in business they would be laid off. This was an entirely new policy for the company, as during the several years of the depression of the early thirties the company had not laid off its workers but had shortened up the working hours somewhat and divided up the work as nearly equally as possible. It was decided that these temporary workers, unless already entitled to medical care as a dependent of an old worker, would not be eligible for medical care, and when they were hired they signed a statement recognizing this fact.

After Pearl Harbor, the loss of so many of our physicians to the armed forces and the difficulty in obtaining any replacements made it necessary to continue the exclusion of these new workers from the medical service. There were not enough suitable replacements available to enlarge the medical department to provide these new workers with adequate medical care. Gradually, however, we have been able to obtain a few additional physicians, some part time and others full time. This, together with the loss of almost 4,000 workers to the armed forces and the migration of many others to industries more closely associated with the war effort, reduced the patient load to a point where the company again decided to return to the policy of furnishing complete medical care to all workers and their dependents if the worker had been in the employ of the company for at least six months on June 1, 1944.

At the present time, then, the following groups are entitled to medical care:

1. All workers who have been in the employ of the company for at least six months.

2. Husbands or wives of workers not otherwise gainfully employed.

3. Children. If the father is an Endicott-Johnson worker, all children regardless of age who are not married or not employed elsewhere are considered dependents. If the mother is a worker and the father works elsewhere, he is considered the head of the family and medical service would be extended to the mother but not to the children.

4. Parents of workers. These have always been a problem as to just who is responsible for their care. If they make their home with a worker and are dependent on the worker for their living, they are usually considered eligible for medical care. Many times, however, there are several children in the family, some of whom work for the company and others work outside the company. Who is responsible in such a situation? Each of these cases is considered individually by the relief department, and if it considers that the responsibility is a divided one between those children working for Endicott-Johnson and those working elsewhere, frequently "limited service" will be extended; i. e., they may have the services of any of the physicians, the use of the facilities at the medical centers but not hospitalization or other service where a definite charge is made to the company. I think that you can see that the line of dependency is frequently a difficult one to draw and early in the history of the department there was some abuse of this extension of the service to dependents, so that occasionally parents not living in the Endicott-Johnson city area who were no longer able to work and who were in need of considerable medical care came to the Endicott-Johnson city area, were classified as dependents of a worker and extended medical services, even though they may have made their home with some other son or daughter before they began to be in need of medical attention. It did not seem as though these cases constituted a legitimate charge against the Endicott-Johnson corporation, and so unless the parents have made their home with the worker for some time and this seems to be their established residence, they are not as a rule extended medical care.

5. Individuals who are employed in the retail stores or the sales division. Such persons who do not live in the Endicott-Johnson city area are eligible for service if they come to the Endicott-Johnson city area, and many of these workers and their dependents do come to the medical centers or hospital for diagnostic study or elective surgical procedures.

During normal times we maintain three distinct medical centers, one in Binghamton, one in Johnson City and one in Endicott. The workers in Owego are cared for by a part time physician and referred to Endicott or Johnson City for any special treatment that may be necessary. In each of the medical centers there are available from four to seven physicians who are considered our general practitioners. Each of these physicians has scheduled office hours of two to three hours each day, and these hours are so arranged that there will be at least one physician in the office for office hours from 8 a. m. to 6 p. m. In addition these physicians make calls at the workers' homes and follow the patients to the hospital whenever their condition warrants hospitalization. Each center has an internist, at least one surgeon, an obstetrician, a pediatrician, an ophthalmologist and an otolaryngologist, who hold regular office hours and see patients as they are referred to them by the general practitioners. Antepartum and postpartum clinics and baby clinics are held by the obstetricians and pediatricians respectively. Practically all deliveries are cared for in the hospital. One syphilologist divides his time between the three centers and not only takes care of the venereal diseases but also performs cystoscopic and other genitourinary procedures. Laboratories approved by the state department

of health perform all the usual blood and body fluid examinations.

In each of the medical centers is a dental department. Here a staff of six dentists and four dental hygienists carry out a program including cleanings, fillings and extractions. Dentures and inlays are not included in this service.

The normal procedure, then, in case of illness would be something like this: The worker calls the medical center and states that his youngster is ill and needs a physician to call at the home. The clerk asks the name of the worker and checks this against a key file which is kept in each of the medical centers. If the name given is listed as a worker and the child as a dependent, the clerk asks which physician is wanted and the call, together with the name of the physician asked for, is listed in the call book. This freedom of choice of physician is given to the worker except when one particular physician has already received enough calls to keep him busy for that particular day. In such case the worker may ask for some other doctor. Many times the patient has not given a preference and then the call is entered in the call book as an open call and one of the physicians who has other calls in that part of the town or one of the physicians who does not happen to be so busy on that day takes that call. From 6 p. m. to 7 a. m. only one physician is on call at each of the centers and takes all the calls received between these hours. This night call rotates each night, so that normally each of the general practitioners is on call one night in six or eight, depending on the center to which he is assigned.

In case the illness is such as to allow the patient to come to the office, he may call the center and ask what time his particular physician has office hours on that day. Each of the physicians has a definite schedule of office hours. They usually are scheduled for two hours at the same time each day except that an attempt is also made to allow each physician to be one hour late in the afternoon so that the workers may see the physician of their choice on at least one afternoon without losing time from their work.

The specialists for the most part spend their mornings seeing patients in the hospitals or in the homes in consultation. Their afternoons are spent in the office seeing patients referred by the general practitioners or other specialists.

On Sunday and holidays one physician is on duty at each of the centers and takes care of all the calls and office work for that particular day. An attempt is made to limit this work to emergencies as far as possible, and the workers cooperate in this fairly well. In the hospital, one man of each of the specialties is likewise on call and attends to all of the hospital work in his particular field.

In addition to the full time men, arrangements have been made with certain specialists for part time duty. In the fields of endocrinology, dermatology and thoracic surgery, specialists from Binghamton hold clinic hours once or twice a week, see patients in consultation as necessary and perform whatever surgery comes within their field.

Most of our specialists started with us in the capacity of general practitioners. Then, as openings in the various specialties have occurred, the general practitioner who is thought to be best qualified is given the opportunity to go away for postgraduate study and then return to limit his practice to that particular field. Rarely the need for men in certain specialties has

been so great that it did not seem advisable to wait for the training of a man, and in those cases men already trained have been employed.

In each of the medical centers there is a complete pharmacy in charge of licensed pharmacists who issue medicines only on prescription. We have no routine procedures; each physician is allowed to treat his patients as he deems proper.

In those cases requiring special care beyond that of our own staff, the patients are sent to medical centers in New York City, Boston, Baltimore, Philadelphia or wherever necessary to obtain the services which we feel are essential for that particular case. All the expenses of such care—physicians' fees, hospital care, railroad expenses and so on—are paid for by the corporation.

Most of the patients who are hospitalized are sent to the C. S. Wilson Memorial Hospital of Johnson City. This hospital was started by Dr. Wilson with the aid of the Endicott-Johnson corporation. On his death, the estate did not feel that it could continue the hospital, so the company purchased Dr. Wilson's interest and then deeded the hospital to a board of managers as a community hospital. Occasionally, in an emergency, patients are admitted to Ideal Hospital, the village owned hospital of the village of Endicott. In such cases the company pays the hospital the usual hospital rates.

When it becomes necessary to send a patient to the hospital, the physician decides what type of accommodation is necessary for the individual patient—ward, semiprivate or private room—and the medical service takes care of the entire hospital bill. If the patient desires more elaborate accommodations than the physician deems necessary, he may ask for such accommodations, and the difference in rate between the two is submitted to him as his hospital bill.

In cases requiring special nursing services, the heads of each department, medical and surgical, rule on the necessity for such services, and if they seem necessary the company pays for such special nursing service.

In addition to the medical department, there is a voluntary sick relief association to which the employee may contribute 25 cents weekly. In case of illness which compels him to remain away from work for more than one week, he is entitled to draw "sick relief" of \$12 weekly for ten weeks. In cases in which the disability lasts more than ten weeks, the company frequently extends relief payments for a longer period of time, depending on the individual case need. No definite pension rate has been established, but each case is considered individually and the general principle has been for the company to supplement any social security payments which the individual may receive with sufficient funds to enable him to live without drawing on any funds which he may have been able to save.

The average cost of this medical service has been around \$48 a year for each worker. In the past two years, however, because of increased costs, drugs, supplies, hospital rates and salaries, it rose to \$57 in 1942 and to \$63 in 1943. The average cost annually per person eligible for service was around \$17 until 1942, when the rate rose to \$19 and in 1943 to \$21.

SUMMARY

An attempt has been made to give to the Endicott-Johnson workers and their dependents a complete medical service without any limitation except for the need of the patient.

The patient-physician relationship has been kept as nearly as possible the same as in private practice. He has a reasonable choice of physicians. He has access to specialists in every field. He is entitled to unlimited hospitalization. He may have unlimited amounts of laboratory, x-ray or other examinations. The entire service is free to the worker, the company assuming the whole expense as an operating cost.

MEDICAL SOCIETY PREPAYMENT PROGRAMS

LESSONS LEARNED FROM EXPERIENCE IN MASSACHUSETTS

JAMES C. McCANN, M.D.

WORCESTER, MASS.

America and our profession are caught in the toils of a cyclically recurring world crisis. In the current phase of crisis we must attempt to discern and anticipate future patterns of medical practice. Only thus can we guide inevitable readjustments into channels which will preserve the basic values and achievements of our free profession.

These challenging days confront us with new demands, three of which seem to have crystallized clearly; first, to produce and distribute, in cooperation with other properly interested agencies, good medical care across the entire face and into all segments of our nation; second, to accept the intent of the American people to transfer medical care of the indigent from its present base of professional responsibility as a charity to a community responsibility through taxation; third, to devise mechanisms which will provide the wage earning and moderate income segment of the American populace with a mode of easy access to needed medical services on a less costly basis. Voluntary prepayment programs under medical society auspices seem to promise much in this latter problem.

1. APPROACH AND OBJECTIVES

Experience has demonstrated the unwisdom of initiating a medical society prepayment program on a complete coverage basis. Nearly all plans have reverted to a partial coverage surgical-obstetric contract with x-ray allowance. Massachusetts has found such a limited contract to afford an actuarially sound experience in types of service not readily abused by unwarranted overutilization, thus protecting the venture during its infancy from serious adverse selection. Massachusetts hopes soon to extend coverage to include hospitalized medical cases; ultimately we should extend coverage to include as much of home and office care as is feasible.

2. SERVICE VS. CASH INDEMNITY

Massachusetts in common with most states has built around the service type of contract as the nub of the effort. It is available to individuals with incomes below \$2,000 a year and to families below \$2,500. Cash indemnity contracts are available above these levels. This dual approach protects a subscriber's permanent eligibility despite fluctuations of income above or below these levels by automatically transferring him from the service to the cash indemnity category and vice versa. Only a service contract for the entire family in the

Read in a panel discussion on "Variations in Industrial Medical Service Plans" before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

lower income brackets under which no extra charge is made beyond the corporation allowance for the service will give needed protection to this group.

Prior to 1942 the American Medical Association had taken no official cognizance of the fact that responsible state societies were building prepayment programs on the cornerstone of a service contract. All statements referred to cash indemnity contracts. To obviate this anomaly, Massachusetts sought and procured acceptance by the House of Delegates of the American Medical Association in 1942 of a resolution which recognized the service contract on a par with cash indemnity contracts. Despite the accomplishment, an editorial appeared in *THE JOURNAL* on Nov. 20, 1943 which disregarded this action and misleadingly stated that "the medical profession has approved . . . prepayment plans on a cash indemnity basis for meeting the costs of medical care."

3. ORGANIZATION

There are professional and legal problems in organizing a prepayment program. On the basis of the experience of Massachusetts proper enlightenment of the profession concerning the program wins adequate professional support. Sufficient committee effort, local county presentations, publication of all plans and placement of printed information in the hands of every physician secured nearly 70 per cent participation by practicing Massachusetts physicians on the basis of signed contracts within a few months time.

The Massachusetts program was established on a statewide basis with no county review. Such review leads to professional dissensions; the public mistrusts a program which disrupts local professional unity; sales forces cannot cope with the handicap of sectional non-participation; public relations are disturbed when subscribers find that services rendered will not be paid for in "forbidden areas"; unlimited patient access to specialists' services may be interfered with by arbitrary limitations at county lines.

Another problem relates to participating and non-participating physicians. Dealing only with participating physicians constitutes the morale basis of the service contract. This practice must be initiated as basic policy and rigidly adhered to from the beginning. In dealing with 35,000 subscribers over a year and a half, Massachusetts thus far has rarely paid for services by a nonparticipating physician. This decision appears to have made our service contract secure to date.

Legal aspects of organization relate to the specific form of corporate structure erected. Some states seeking professional jurisdiction over purely medical problems have gone to the extreme of creating boards of directors with physicians constituting a majority, up to three fourths or more, of the board. This deprives the board of valuable nonprofessional points of view and maximal public confidence. Massachusetts, weighing the corporate powers of voting members versus boards of directors, created a directorate composed one third of physicians, one third of subscriber representatives and one third of eminent business leaders. The executive committee of the medical society was given the voting membership of the corporation, empowered under the by-laws to elect the board of directors and change the by-laws. This voting membership of doctors has a guaranteed position as an advisory committee on strictly medical matters, since action in the medical

sphere contemplated by the directorate is reportable to the voting members thirty days prior to definitive action.

4. RELATIONS WITH BLUE CROSS

Massachusetts Medical Service established the closest contractual relations with the Blue Cross. The executive director of Blue Cross is also director of our corporation and provides administrative and sales services. This interrelationship seems reasonable on several counts: administrative costs should be significantly reduced; public acceptance of Blue Cross should be an effective entrée for a medical service corporation; business organizations prefer single sales approach and single payroll deduction for the joint services; sales to established Blue Cross groups should be most effectively accomplished by Blue Cross salesmen. The "should" in these statements relates to the unsettled problem of whether or not Blue Cross, even with the best of intentions, can give adequate sales time and effort to medical service contracts while seeking the highest sales volume of Blue Cross contracts.

Effective contractual coordination of medical service corporations with Blue Cross must be made in the face of divergent philosophies. Blue Cross executives favor an intimate interlocking of the directorates of the two corporations, even to the point of creating a single corporation to sell both hospital and medical service contracts. Physicians are well advised to create separate and distinct medical service corporations until the evolution of an experiment, so portentous in its bearing on our future professional destiny, is complete. Blue Cross executives do not sympathize with the profession's belief in the need of income limits for the service type of medical contract. Some Blue Cross plans are selling a cash indemnity contract of their own to supplement contract with local medical approval. A comprehensive hospitalization contract which includes payment for hospital-medical services, which appear as items on the hospital bill—pathology, anesthesia and x-ray—is contemplated by Blue Cross.

In resolving these controversial matters there should be thorough exploration of the wide area of common interests between us before we fall out over restricted areas of technical disagreement to our ultimate mutual confusion. Solutions may possibly be arrived at if discussion is based on the following premises:

1. Hospital billed medical services are delivered by practicing physicians who themselves have freely arranged their varying contractual relations with the institutions.

2. The Blue Cross and medical service corporations are strictly financial agencies entirely devoid of facilities, so that they do not distribute hospital or medical service directly per se. Therefore they should not be involved in the controversy relative to hospitals encroaching on the field of medical practice.

3. The two types of corporations seek by contracts with hospitals and physicians to take up the total cost of services rendered within restricted categories, with the understanding that no further charges will be made, thus giving the subscriber the so-called "service" coverage. Secondary financial contracts of this character by which Blue Cross seeks to take up any cost item on a hospital bill which is partly a hospital and partly a medical responsibility does not per se constitute encroachment on medical practice, provided such a secondary contract does not infringe on the terms of

the prior existing contract executed between the hospital and the physician. Since it relates to a pure financial transaction after the fact of delivery of a service, it cannot properly be construed as introducing a third party between the patient and his doctor or hospital.

4. Medical service corporations can never take up completely the entire cost of all the special medical-hospital services, because this would divert a disproportionate part of the subscriber's premium contribution intended for medical services to direct subsidy of elaborate hospital equipment, space and personnel.

5. There is a dual responsibility resident between the Blue Cross and medical service corporation to make these medical-hospital items available to the public on a service basis through a prepaid contract in the same way in which strictly hospital and strictly medical services are being made available.

6. These problems might be resolved if Blue Cross allowances for such items in hospital bills were made on three bases:

(a) Contracts should specify that allowances are for the cost of services (not for the provision or sale of the services per se).

(b) Descriptive circulars should explain that allowances paid the hospitals are to be allocated by the institutions according to existing contractual arrangements between the hospital and the physician who delivers the professional service.

(c) Safeguards should be erected against insurance stimulus to hospitalization of properly ambulatory patients who would normally be examined (say by x-ray) in the physician's office. Otherwise there will be costly and unwarranted hospitalization for ambulatory illness, with consequent aggravation of hospital crowding at the expense of private medical practice. This might well prove disastrous in the long run, because in well authenticated instances the establishment of a private laboratory by the physician has been his only means of escape from an inadequate unilaterally established contract, imposed on him by institutional shortsightedness. To jeopardize this professional "safety valve" might threaten the survival of a basic specialty in medical practice.

ACCOMPLISHMENTS

Medical society prepayment programs constitute a young movement not yet sufficiently seasoned for appraisal. There are statewide plans in sixteen states, with seven local plans in three other states. Total membership is about 1,000,000, with Michigan's 600,000 constituting over a half. Massachusetts has enrolled 34,000 persons since January 1943 based on about 15,000 contracts. Whereas Michigan's huge enrolment is 90 per cent in eighteen large industrial groups, ours is distributed through three hundred and ninety-six groups. Our largest group enrolment is 150. The average number of contracts per group is 37.6, and the average number of subscribers per group is 85. In 1944 our enrolment has averaged 68 per cent of the enrolled groups.

Massachusetts Medical Service has operated during this period entirely in the black. Selling our surgical-obstetric contract at the monthly rates of \$0.85 for the individual, \$1.65 for man and wife and \$2 for the family, we have retired our organizational expense of approximately \$5,000 and created a reserve and surplus of nearly \$35,000. Our position seems sufficiently strong, so that recently the directors deleted all exclusions relative to preexisting conditions from the subscriber's contract. We hope in the near future to make some provision for hospitalized medical care.

From our experience the financial soundness of any state society program will be related in general to

several items: first, the adequacy of the premium structure as related to the services offered and the compensation to the physician; second, the utilization rate by the subscriber, which will be determined by (a) the seasoning or elimination of preexisting surgical needs by prior Blue Cross or other insurance coverage and (b) the level of professional-public health-hospital services which determine the legacy of medical liabilities confronting the new corporation; third, the proper discharge of responsibility by the directors in adequately balancing the premium rates, administrative costs and contract benefits; and, fourth, adherence to a fixed schedule of allowances to physicians for standard services so that a solid actuarial experience may be evolved.

This short experience in Massachusetts suggests the promising value of a medical society prepayment program for the following reasons:

1. Because it is based on acceptance of a responsibility by the producers of medical service, who are guided by a code of high ideals and ethics and who usually exhibit an adequate sense of social and community responsibility.

2. Because it provides a pattern which can be made universally applicable in urban and rural areas, over short or wide distances, in large and small communities, in larger or smaller business units, in upper or lower income groups, the indigent and special governmental groups.

3. Because it creates a mechanism whereby medical care on a service basis can be provided for that income segment of the population in need of such protection without disrupting medical freedom, relations and establishments.

4. Because it encompasses such controversial medical modes as group practice versus individual practice and fee for service versus salary compensation, neutralizing this potent principle of prepayment with reference to each until these problems are resolved in the normal competitive evolution of medical practice.

5. Because it best safeguards the freedoms inherent in our American system of medical practice during this tragic interlude in which our republic must resolve its epic dilemma—whether to continue as a free enterprise, individualist society or to shift to a preponderantly socialistic, authoritarian type of state.

6. Because, if the former choice is happily made, medicine can adapt itself to current evolutionary change in democracy. A change by which community or governmental responsibility and enterprise on a federal-local basis shift from laissez-faire inactivity to that of umpire in cooperative efforts between the community and those free enterprise groups which exhibit the following three marks: (1) self-imposed discipline by the individuals who compose economic groups as far as group social responsibility is concerned, (2) acceptance in full measure by the group of its entire social responsibility as determined by community needs and welfare, and on a basis acceptable to the community; and (3) group cooperation with all rightfully interested agencies, whether governmental or private, in adequately meeting community needs. Selfish, indifferent or irresponsible groups will lose all right to free enterprise by default, and complete governmental action will supervene. To this current phase of our evolutionary democracy, medicine must pay heed!

St. Vincent Hospital.

VARIATIONS IN CURRENT INDUSTRIAL
MEDICAL SERVICE PLANS

JOHN J. WITTMER, M.D.

NEW YORK

None of us are afraid of ghosts. Our scientific training and intellect does not permit us to give credence to tales of preternatural caterwauling or mistlike apparitions. As children we all listened to or read ghost stories, with the usual glandular reactions, but have long since learned that all such evidences of abnormal psychology can be "laid by the heels" by the application of a little practical logic.

I am going to present a practical method by which we of the medical profession can banish the ghost which has haunted American medicine for so many years—can, in the traditional manner, drive a stake through the heart of government controlled medicine and silence forever its oft repeated threat to the traditional control of medical practice by the profession itself.

This specter of government control has not suddenly appeared on the horizon but has been gradually materializing, disguised as a panacea, for many years. In the past, opposition has been able to force it to retire into the background, but on each occasion of its resurgence it has been able to loom a little higher, until now not only has its head appeared but also most of its body. How much longer will it take for the legs to appear and for the apparition to materialize into a living Frankenstein, able to walk among us and become the potent, dominating factor in our work and our lives? I myself can already see the embryonic legs taking form.

We will not get rid of this specter by calling it base names, by proclaiming that it is unworthy and debasing or by hacking at it at random. It would seem that the more it is hacked the faster and stronger its limbs grow back again.

I think most of us must realize that the only way that we can stifle the growth of this being is to create an acceptable entity of its own kind having its own weapons—one which will not only take its place but will so far outshine it that the apparition will vanish in the brilliance of the plan of our creation. In terms of military strategy, our best defense is a vigorous offense!

I honestly and implicitly believe that the present trend toward socialized medicine can be completely "outshone" by a properly and strategically worked out plan of voluntary health insurance. Not health insurance that covers only part of sickness but an all out plan which completely and comprehensively covers all phases of illness and health—a plan which will have a budgetary basis that will insure an income commensurate with the doctor's education, qualifications, maintenance of social level and the vast expenditure of time and energy and yet not be so costly that it will be beyond the average subscriber's financial reach; health insurance that includes the medical fraternity as administrators. I believe a plan can be worked out along these lines which would nullify any inherent paradox which some may claim exists in the situation, would be attractive to the layman and would benefit our profession immeasurably by comparison with government control.

I need not point out that the poor receive excellent medical help from our profession at little or no cost and that the rich can afford to obtain any medical aid which they desire. The middle class individual, with his constant current economic demands, is neither so poor that he can obtain free aid nor wealthy enough to stand the rich man's prices. However, we have all noticed a trend toward an ever expanding group of so-called "indigent people" which includes many middle class people who, we know but cannot readily prove, can really afford to pay moderate medical fees. There is no doubt in my mind that many people admitted to charitable institutions and municipal hospitals could probably afford to pay all and could certainly pay part of their medical costs. We, as doctors, are aiding the expansion of this group of "tailor made mendicants" by continuing to donate of our services to those "indigents" who are undeserving.

My opinion is that that no one who has any income whatever should be allowed to obtain free medical aid. He should pay in proportion to his income, no matter how small the income may be. However, medical catastrophes do not come in 98 cent bits. Reasonable charges sometimes amount to hundreds of dollars. The \$25 a week man never has a hundred dollars—at least for this purpose. He does, however, have 50 cents a week that he could contribute as his share—a share that in time cannot help but make up the hundred dollars.

Generally speaking, the "great" middle class deserve a break when they are faced with illness or injury. If they are allowed to work out prepayment medical plans, each will contribute his share and, for a change, the medical profession will be paid for all services rendered, except to the genuinely poor.

Many years ago in the Consolidated Edison Company we realized that we had a very large group of employees who did not have the wherewithal to finance expensive operations or protracted treatments but who could afford to contribute something regularly each week toward their medical care. Many times we advised employees to have tonsils removed because we felt that they were the focus of infection for generalized arthritis, to have abscessed teeth extracted for the same reason, to obtain x-rays or other laboratory data required for proper diagnosis—only to hear them say, truthfully, "That's fine, but where am I going to get the money?" At that time the average income of our workers was as high as and probably higher than the income of workers in most industries, but about the only thing we could do was to try to arrange with some semicharitable or city institution to have the work done with no, or at least very little, expense to the employee. You know that this condition exists in all communities. Who has been doing this free work? You doctors sitting here before me today!

We of the Consolidated Edison Company of New York, Inc., saw a solution of the problem when the rank and file workers—those earning less than \$3,000 a year, asked permission to form a mutual aid association. The entire arrangement was voluntary. A worker had absolute free choice of joining the organization. As a member he paid five ninths of 1 per cent of his weekly salary, which averages about 22 cents a week. The company felt that it would gain enough from the experiment to match the weekly contribution of the employee. For this contribution the employee was eligible to obtain a total medical and a basic dental service. The doctors and dentists were provided on

a restricted basis, which is to say that a group of doctors was selected to work on such a part time basis as was felt to be adequate to take care of the illnesses of all the subscribers. By "part time" I mean that enough potential work is available to occupy the doctor for about a third to a half of his working hours. Members are allowed to select any one of the doctors on the group whom they choose. The same system applies to the dentists.

Of course it follows that within a short time one doctor has more work to do than another. This naturally occurs according to the interest and sincerity which the doctor puts into his work, and, because the doctors are paid on a fee basis, competition is keen. When necessary, members are free to choose specialists who cover all phases of consultant medical work and who also are in the group.

Our entire medical service is under the absolute authority of a medical director and his assistants, all physicians and surgeons in good standing. The medical staff includes physicians, surgeons, dentists, nurses, pharmacists and a masseuse, besides the clerical staff needed, all except the last being on a fee or retainer basis. In addition, physicians attached to various hospitals treat our employees and receive payment on a fee basis for their services.

The medical services available are:

1. Physical examinations before transfer, retirement or for special reasons.
2. Periodic examinations, including those for certain types of workers, such as men engaged in hazardous occupations.
3. Examinations requested by employees.
4. Examinations prior to return to duty, including routine fluoroscopy.
5. First aid for injuries or illness on the job.
6. Treatment for illness, either in one of the medical bureau offices, at a physician's private office, or at home.
7. The furnishing of prescribed drugs.
8. Diagnosis and treatments by specialists.
9. Extensive x-ray and laboratory facilities.
10. Cooperation with employees' personal physicians in cases in which the employee still chooses to have his personal physician, and advice on home medical problems.
11. Physical therapy service under the direction of a physician.
12. Dental diagnosis, treatments and restoration work.
13. Operations, medical treatments and other services in hospitals.
14. The facilities of a convalescent home under medical supervision.

During the time that our medical service has been in operation, our observations and personnel statistics have indicated a decided improvement in health conditions in a working force that now approximates 25,000 employees. Serious chronic illnesses, such as tuberculosis, cardiovascular disease and those due to toxic poisoning, have been reduced greatly. Our doctors rarely find the deplorable cases of neglect of teeth, mouth, throat, alimentary canal and the degenerative conditions due to tonsils or other foci of infection. Our absentee rate is well below the national average.

Our medical services are extensive, and the employees use them freely but, consisting as they do of essentials only, the services are not a tremendous burden financially either to the employees or to the company. All the services outlined can be obtained at a total cost

for each employee of approximately \$22 annually. Since employees contribute to the cost of the medical service, they feel that it is theirs to use, and both the management and the employees benefit by a sounder, healthier body of workers.

The question naturally arises: What are the advantages of such a program?

Let me list them:

I. Every employee in the middle and lower income brackets is paying his way when he is ill. We do not have employees who are being treated in charitable or other free institutions. I really believe that a third to a half of present medical mendicants can be changed to paying clients by a prepayment medical plan.

II. The doctor's income is higher. He is receiving an actual income for the actual work he does. There are no debtors on his books. In addition, he is receiving pay for work that he formerly performed for nothing.

III. In all these plans there is money available for research and prevention. This money is available as part of current expense and can be used in ways that are deemed most feasible by the medical fraternity.

IV. As all aids of x-ray laboratory and other diagnostic facilities are available without monetary restraint, an immediate and reasonably certain diagnosis can be made. Not only is this a gratifying reward in the practice of medicine, but the patient is that much sooner available for efficient productivity in industry.

V. Patients will seek medical help earlier in the disease and in some cases more often. Early diagnosis, concentrated treatment, unlimited facilities and freedom of action allow the doctor to get more patients well much more rapidly.

VI. By exercising all methods of prevention, immediate and comprehensive diagnosis and concentrated treatment, we feel that our absence rate is about one half of that of the average industrial worker. This, of course, helps industry, but what helps industry helps the community and cannot but be an asset to the country as a whole. In addition, the employees are perfectly satisfied with this program and, I firmly believe, would vigorously oppose any other plan. The only dissatisfaction that exists is that we have not included the members of the family.

VII. Constant check-up of employees reveals many hidden conditions which, while not totally incapacitating, do retard their efficiency. Correcting these conditions in their infancy is prophylaxis against present loss of ability to produce and future lost time.

In conclusion let me leave this thought with you. If voluntary health insurance in the form I have described is worth while, and I sincerely believe it is, it should be adopted wholeheartedly by the profession. I do not believe that we shall get anywhere by watching small experiments proceeding in a few isolated areas. The present problem calls for prompt action: action to proceed with these plans in an extensive, organized manner; large plans that cover many people in many places. Let us beware that while we are too carefully and slowly scrutinizing what seems to be a real answer to our problem we might have saddled on us this "speeter," this more radical substitute which has taken hold and which, as legislation, would have to be accepted "whole hog."

Let us, as the caretakers and guardians of the health of the American people, work out a "modern way" of

medical care for all our people with due consideration for their financial resources, with adequate provision for their proper care, with provision for an adequate income for the doctor and, last but not least, with a view toward preserving the dignity of our profession. This is our precept, our prerogative and our duty.

4 Irving Place.

QUESTION AND ANSWER PERIOD

ON PANEL DISCUSSION ON VARIATIONS IN INDUSTRIAL MEDICAL SERVICE PLANS

Question.—What is the attitude of the local profession to the association?

DR. JAMES M. ADAMS, New York: At the time the association was organized there was passive resistance on the part of the local medical profession which a few years later became active; however, I am pleased to say this has entirely vanished now and the association is recognized as a part of the medical life of that community.

DR. M. S. BLOOM, Binghamton, N. Y.: The plans have been set up with complete freedom of choice. They have never been set up in any community without first taking it up with the economics committee of the county medical society. The doctors have welcomed the plans. Recently, before care for dependents was added to the Anso plan, I had meetings with the surgeons and the eye, ear, nose and throat specialists saying that, if they were willing to cooperate as they had with the employees, we would put it to a vote of the employees. The doctors agreed, the vote was taken, and care for dependents was added to the benefits of the Anso plan.

Question.—How did the unions feel toward the prepayment medical plans?

DR. BLOOM: Very well. Some of the plans were in operation before the union was established, and the unions insisted in their contract that the plans be continued as before.

Question.—Will the long term instability of industrial units and of employment restrict the value of industrial units as a base on which to build medical care?

DR. JAMES C. McCANN, Worcester, Mass.: My reaction is based on living in the oldest industrial section in the nation, New England. I live in Massachusetts, which was once the heart of the shoe industry and the cotton industry but is so no longer. I came from Maine, which was the heart of ship-building, but Maine has lost out to the Pacific coast. So there is a tremendous instability in industry, if we look at it from the point of view of constructing the medical care of the American people around that base. Mr. Henry Kaiser became interested in this problem, and he did establish a prepaid medical group on the West Coast. As president of Brewster he didn't. Since Brewster has just lost its contract for the construction of the Corsair airplane, since it is estimated that if the airplane industry will continue at 20 per cent of its present productive capacity in peacetime it will be fortunate, I wonder how stable that is as a long term base for revising the distribution of medical care. I know that key figures in major industries in New England are totally unwilling to become involved in this problem. Most do not want to become involved in any step encroaching on the tremendous problem of local medical care.

Question.—Would the long term instability of industrial units and of employment restrict the value of industrial units as a base on which to build medical care?

DR. JOHN J. WITTMER, New York: Industry isn't in the mood to take over this medical plan. Industry wants the community to do it and I myself feel that it is a community problem and that the community itself should organize to do it. The only reason industry has gone ahead on the present basis is that the community and other sources have not solved the problem and industry was forced to do it.

DR. SIDNEY R. GARFIELD, Oakland, Calif.: Mr. Kaiser and I both feel that medical care should be on a community basis. The plan we propose that the medical societies should operate, utilizing the principles we think are sound in operation, should

supply not only industry but the community—the Lions Club, the Women's Club, the farmers' cooperatives—every organization possible that can arrange for collections of dues.

Question.—Why do you use a three thousand dollar limit for employees who join your plan?

Question.—Is a \$2,000 to \$3,000 income ceiling necessary?

Question.—You mentioned five ninths of 1 per cent by employer and employee as a contribution to support the service. Is there any top limit of earning beyond which the percentage does not apply?

DR. WITTMER: We decided on the \$3,000 limit as a method of expediency backed by practical experience. The reason we said \$3,000 in the beginning of our plan is that we have two methods of payroll payment: Those who receive less than \$3,000 a year are on a weekly payroll, those who receive \$3,000 or more are on a monthly payroll, and it was much easier to draw the line and say those on one side should be members of the plan and those on the other side would not. In addition is the fact that the average man who gets to \$3,000 in the non-war-time period is usually an older man, 45, 50, 55, and usually he has reached the height of his family experience. He already has his two, three, four, five and six children. The man of the lower income bracket in quite a few instances doesn't have quite as many children. In interviewing these various individuals we found from the level of their living that they needed more money than the laborer would who is earning \$2,000 a year. We found that our loan ratio was much higher in the \$2,500 to \$4,000 group, that those were the people who really were borrowing money. We think \$3,000 is certainly the lowest level of payroll that should be used as a ceiling. The question on five ninths of 1 per cent—that sounds rather ambiguous—but if a man is earning \$27 a week he pays about 15 cents a week; if he was earning \$18 a week he would pay something like 10 cents a week. When he gets into the \$40 to \$45 group he still pays his five ninths of 1 per cent, which, of course, is actually more in that it is the same percentage of a higher amount of money.

DR. McCANN: We established \$2,500 in Massachusetts. We found out afterward from union men on our board that \$3,000, roughly, draws the line of demarcation between the working group and management, and that if one has an income limit below that one would be asking the union by supporting it to introduce a factor of apparent discrimination in approaching the workmen.

Question.—Is there a tendency on the part of attending physicians to charge in addition to the amount allowed by the plan?

DR. BLOOM: Only occasionally do physicians outside the direct localities charge fees higher than those allowed. We are paying bills to physicians throughout the United States. We pay the allowance, and the patient pays the difference. The executives in the various companies are included in the plans. We don't expect the doctors to charge consistently the fees outlined for the workers.

DR. ADAMS: We have a number of plans in our company that were based on the plan outlined by Dr. Bloom. Most of those have a maximum for surgical operations of around \$150, and the surgeon's fee is usually paid up to that amount; also set fees for house visits and office calls, and in most of the communities where these organizations operate we find that the charges of the physicians are seldom greater than those allowed by the association.

Question.—Is absence or sickness rate lowered as a result of the plan?

DR. ADAMS: I don't have the figures, but I can say in a general way that my close association with the Stanocola plan was in its early stages and at that time we did notice a definite drop in the sickness rate after the inauguration of the plan. Whether this was a direct result of the operation of the plan I am unable to say.

DR. BLOOM: Yes. Under the Anso plan we had a gradual drop over a period of eight years. Less sick relief was drawn each year. We have no way of determining from the Mutual Benefit Association's data absenteeism for less than seven days. I should like to give the exact figures on sick benefits from

1934, when the average amount drawn annually per member was \$3.75. This amount gradually decreased until 1940, when the amount drawn was \$1.41 annually per member.

DR. WILLIAM A. SAWYER, Rochester, N. Y.: Per employee?

DR. BLOOM: Yes.

DR. WITTMER: I can say definitely that it is lowered in our plan to about half of the national average in spite of the fact that we have a liberal sickness payment plan. A man is entitled in any current year to one week's full time pay for each year that he has worked and after that period has expired receives twenty-six weeks in any current year from his mutual aid society at 80 per cent; in other words, if a man has been working for the company for twenty-six years he is allowed when ill twenty-six weeks' full pay, twenty-six weeks' mutual aid at 80 per cent.

DR. EDWARD M. JONES, Johnson City, N. Y.: Such figures are difficult to interpret because of the many factors involved. Although I have no statistics on our plan, I doubt whether it makes any difference in the absence rate from work. One important factor, particularly when women workers are involved, is the approximation of the sick relief rate to their weekly wage. During the years mentioned by Dr. Bloom this is a factor to consider.

DR. BLOOM: Our experience in the shoe industry shows that absence or sickness was reduced during the depression because people were afraid of losing their jobs. Our sick benefits were much lower then than during other times.

Question.—How are the doctors paid under the Consolidated Edison plan?

DR. WITTMER: The doctors are paid on a fee basis for each call they make. They make a report on each call, and a record is kept for monthly payments.

Question.—How can one give complete care to needy people without taxation carrying the load?

DR. GARFIELD: A certain proportion of the weekly fee can be set aside for the particular purpose; in other words, we have been able to do a certain amount of work for the needy. Right now, when there is full employment, one could have 5 cents a week set aside for medical care if they are later unemployed. The other way of handling it would be through the Social Security system, where the Social Security setup would pay the fee per week of the person who is unemployed.

Question.—What difficulty has been encountered in a fee basis plan of too much medical care, needless surgery, and the like?

Question.—What limitations as to length of disability should be imposed on disability based on psychosomatic disturbances?

DR. BLOOM: There is always a certain small percentage of employees who will do a lot of shopping around and who will go to doctors whether they belong to prepayment organizations or not. We have found that where there are certain limitations to what the employee is entitled to (and I think the plans I have suggested are rather comprehensive) we do not find that the employees exceed the limitations imposed very often. As Dr. Garfield said on the question of diminishing returns, with the new methods of treatment the number of days' hospitalization will be reduced. Where we have a limitation of hospitalization and of calls, the patients exercise judgment in order to maintain a reserve just as anybody with a certain amount of money in the savings bank exercises judgment and caution.

DR. GARFIELD: We have no particular problem on this point, since all our physicians are on a budgeted income. There is no possibility of overtreatment. They just treat a patient as much as necessary. We have quite a lot of psychosomatic disturbances, which we handle in the usual manner, with psychiatrists, and it isn't a major problem. We have found that hospitalization under our plan really increases; however, it is for minor conditions rather than major ones. It is for a shorter period of time and as a result ends up in being less costly to the organization.

Question.—In actual experience many acute illnesses rarely last two weeks unless complications ensue. It would seem that elimination of the seven to ten days is an element of weakness from the point of view of prevention. Why not have full coverage under the prepayment plan?

DR. WITTMER: I think this question has been misdirected, because we have full coverage. I believe in total coverage not only of the medical service but for the absence. A man who is sick can't get well quickly if he realizes that he is getting \$12 a week rather than his usual \$40 a week. I think paying him his regular salary from the day he is absent keeps his morale high. I don't believe there should be any limitation on medical service. I don't know what these people would do if you should say you would take care of them for twenty-one days or for \$150 worth. At the end of that period, if they really were still ill, they would be up against it just as much as in the beginning. I think that most of the limitations on coverage are in the line of policing, and restriction on service is the poorest kind of policing I know of.

THE CHAIRMAN: I think this question has to do with the rather general policy of a waiting period. One of the speakers mentioned a waiting period of several months, I think, or that the patient had to be employed several months before he became a beneficiary of the plan. The questioner probably had that rather general principle in mind.

DR. BLOOM: It has been the policy for years to pay sick relief only after the first seven days' illness. It must be remembered that the employees themselves draw up these rules and regulations. They feel that it would not be fair otherwise. The purpose of the mutual benefit associations is primarily to provide medical care and to relieve the worker of worry. Medical care is provided whenever the employee desires it.

DR. ADAMS: Our company has preemployment examinations, and in the prewar time any person who applied for membership in the Stanocola Association immediately when he was employed by the company had a waiting period of sixty days. He had to pay dues for two months, in other words, before he could receive the benefits. Since there has been the shortage of doctors in the war period and so many transient workers coming and going, every one is made to wait a year now before he can apply for membership.

Question.—Should any distinction in fees be made to provide incentive for good medical care?

DR. GARFIELD: I don't think I am the proper one to discuss that. We don't work on a fee for service basis.

THE CHAIRMAN: In other words, you don't think it necessary?

DR. GARFIELD: I think the fee for service basis is definitely wrong in caring for medical needs of the people.

DR. BLOOM: If the fees are high enough and suitable to the leading physicians in the community, there should not be any trouble getting the outstanding men in the community to do the work.

Question.—Do employees object to percentage premium payment, that is, the higher brackets pay more than the smaller?

DR. BLOOM: I think I am the only one who has that system. Our members pay 15, 20 and 25 cents a week. Dues are determined by wage scale. This includes cash benefits also. Members cannot join a group higher than their wage level. If there are members who belong to other organizations that pay sick benefits, it has a tendency to encourage malingering. We seldom have difficulty on the question of sick benefits for male workers.

DR. WITTMER: We have the percentage, five ninths of 1 per cent, deduction plan. We have 99 and a fraction per cent of our employees eligible in the plant. This is an absolutely voluntary plan. In the last fifteen years I have never heard any reaction against the variation of deductions.

DR. DEAN A. CLARK, U. S. P. H. S., Washington, D. C.: There is no question in any of our minds that the executives and participants in these successful plans deserve not only our respect but our heartiest congratulations. Nevertheless there are some problems raised by our chairman's address yesterday and by some of the problems implicit in what was said today that are not answered or perhaps cannot be answered by such plans as these. For instance, all the speakers, I believe, spoke in general terms implying that this type of plan might solve the medical care problem for the United States. Then various groups were discussed separately, such as the indigent, the chronically sick, the aged, psychiatric cases. We heard from

our chairman yesterday of the problems of the rural areas, poor states and the regions that under almost no conceivable circumstances could finance their own medical care. And yet all the speakers favor a community type of plan. How could it be conceivable that on a community plan basis, and by "community" it might mean a city, a county, a state or the nation, such medical service plans could care for all our medical problems without taxation and necessarily federal tax aid?

DR GARFIELD. The Kaiser plan would not solve the problem of medical care completely, however it would so nearly do so that the problems not taken care of, such as indigent medical care, could be handled easily through community support. In California if there was a statewide plan operated on the same basis as ours there would be sufficient funds developed within the plan itself to take care of indigents in this state. There may be some states where there is not a sufficient concentration of people to build up funds through such a plan to take care of the indigent and unemployed. In these exceptional instances government help through tax contributed funds may be thoroughly justified. I don't think government intervention is justified or desired if we can do the job ourselves.

DR FRANCIS M. POTTINGER, Monrovia, Calif. The industrial service plans described in this panel are attempting to solve medical problems which affect the efficiency of industrial workers in individual organizations. However, the medical profession today is confronted not by a limited but by a general situation which calls for a complete medical service providing both prevention and treatment for all the people. The experience of limited groups is valuable, but the Massachusetts plan is an attack on the problem which is interesting the medical profession as a whole. Any satisfactory plan must be applicable to conditions of both full and limited employment and also to those of unemployment. It must be suited to the income which the people may receive under all working conditions. It must furnish services not only to workers in large industrial organizations but to all others with small incomes. An important though insufficiently recognized factor in precipitating the medical problem in the last decade is the rapid industrialization which has taken place during the twentieth century requiring the moving of the workers from the country to the city. In 1900 30 per cent of the people lived in the cities. By 1930 this had been increased to 50 per cent. In the country the worker could raise much of his own food, but the city dweller loses his independence by the transfer and is obliged to spend far more for his maintenance than the rural worker, and when he loses employment he is unable to maintain himself and his family. In times of full employment unpredictable illness is hard for the workers to meet and in times of unemployment it is all but impossible. The medical profession has long assumed what is rightly the government's obligation: the care for those of low income and no income. It is an injustice that it should carry this burden, for the preparation for the practice of medicine today requires a large outlay for which the physician deserves adequate return. Furthermore, today's practice, with its laboratories and technicians, is carried out at a cost which the physician cannot absorb in a fee that the average family can pay. In solving this problem the medical profession fears governmental control of medical practice. At the same time there is no way in which it can furnish adequate care to low income families except as charity or through taxation. The objection to governmental control might be overcome by the adoption of a three point program: (1) private practice, (2) voluntary insurance, (3) care for the remaining portion of the population through general taxation. In this plan the medical association could enter into contract with the state to supply the needed care and so would control medical practice and become a more efficient force in the prevention of disease. The government would meet the bills, being held responsible as it should be, for the solution of society's problem. The two together could provide adequate working arrangements and would be responsible for their efficacy.

DR KINGSLAY ROBERTS, New York. I believe that we have heard many things that emphasize the importance of bringing community administration into closer contact with the employer sponsored plans because, by the mutuality of interests, the problems raised about the care of the lower income groups become

community problems, and since the management is also on the administration it becomes something that the community and management can learn to try to work out. I think we can realize from what has been said the great need for more data, more statistics to show just what an active health conservation and preventive medical program, in conjunction with these industrial plans, can mean in terms of dollars and cents. When I go to some one like Dr. Garfield and say that I believe one should spend more time in lessening the incidence and severity of disease I would like to be able to pull out of my pocket a ledger which will show Dr. Garfield and Mr. Kaiser and Endicott-Johnson and anybody else that by spending money we are lessening the incidence and severity of disease and that by so doing they will ultimately save money for their plans.

DR CHARLES V. CRASFER, Newark, N. J. In Newark for a number of years we had a plan whereby the indigent poor and the near poor were taken care of by a group of physicians who were paid an annual salary. There was so much abuse and so much discontent and various other difficulties in connection with such work that we decided to change, and by arrangement with the state medical society we now have a plan whereby the indigent poor and the medically indigent, as they are called, the lower salary groups, will be taken care of by the city on a payment plan which is much the same as that received by the doctors in their private practice. The indigent poor and the medically poor are allowed to make their own free choice of physicians, and the city will pay the fee of these physicians. Of course, the indigent poor are given the service entirely free, but the medically poor are investigated by the welfare department and where they are found to be able to pay some part of the fees they are billed for that amount. The plan has been in operation only for the last six months, but so far we feel that it is giving us the answer to a condition which has been troublesome for a number of years.

DR DAVID A. MCCOY, Boston. I was disappointed in the role of preventive medicine in these particular plans. Organized medical control measures are necessary in any industrial plant not only to serve as a stopgap against occupational disease but also to offer a formidable barrier against the nonoccupational diseases which cause so much absenteeism. I don't think any program either locally or nationally will be successful unless this particular branch of the program is developed.

DR C. RUFUS ROREN, Chicago. I am director of the Blue Cross Hospital Service Plan Commission. The commission, which is part of the American Hospital Association, has been collecting data on the administration and particularly the administrative operation of the medical plans. It was done with some reluctance, because we felt it was not particularly the province of the Hospital Association to explore this field, but the plans were looking for groups which had facilities and some experience to do this. Dr. Wittmer did not say so, but I think we can take it for granted that, although people pay different sums into the operation of the mutual benefit association, the amounts paid on their behalf to doctors are identical. As far as the medical profession is concerned, the payments received on behalf of the low income subscribers are the same as for others. The practice of establishing an income level of \$3,000 in Social Security legislation has been based on the theory that the balance will be made up from some sort of general taxes. There could be a uniform percentage applied to all income groups, even up to \$10,000 (which is, for statistical purposes, the top limit of earnings in the United States), and down to zero. But such a procedure would need to be universal.

DR MCCANN. We must not allow the unchallenged assumption that all the problems of medicine are related to reorganizing the profession on a group basis to pass as valid. That is begging the whole question. I was trained at the Mayo Clinic. I know its values. I practiced group medicine for several years after I left. I am now practicing on my own. I have equal devotion to the individual physician practicing by himself. There are fields for both modes of practice. The men who have been long in the practice of group medicine do not say that the whole profession should be reorganized on a group basis. Some say that the base of medical practice is the general practitioner. I think there will be major important diagnostic centers for reference work through the nation but I think the

backbone of American practice will continue to be the individual practitioner in the community and in the segment of the community where he is immediately available to the family. With regard to preventive medical service, if early diagnosis and early treatment will be stimulated by these methods we are contributing to preventive medicine.

DR ADAMS. The discussion this morning has been limited to industrial and state plans, but there are several other types of plans which may have more universal application than any of these. First probably would come the plans organized and sponsored by physicians themselves, some of which are operating successfully throughout the country, and then other state-wide medical association plans such as in the state of New Jersey. Third are the commercial insurance plans, of which there are many, one of which is operating satisfactorily in our company. Their rates are considerably higher than in our employee organizations, but they are an answer in some states where employee organizations are not permitted.

THE THERAPEUTIC EFFECT OF PARA-AMINO BENZOIC ACID IN LOUSE BORNE TYPHUS FEVER

LIEUTENANT COMMANDER ANDREW YEOMANS
(MC), U.S.N.R.

LIEUTENANT COLONEL J. C. SNYDER
MEDICAL CORPS, ARMY OF THE UNITED STATES

MAJOR E. S. MURRAY
MEDICAL CORPS, ARMY OF THE UNITED STATES

CAPTAIN C. J. D. ZARAFONETIS
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND

MAJOR R. S. ECKE
MEDICAL CORPS, ARMY OF THE UNITED STATES

Many efforts have been made to find a substance of therapeutic value in typhus fever. The papers in the literature which cite the effects of various agents have been discussed in a recent editorial.¹ It is our purpose in this report to present the results of the treatment of classic epidemic louse borne typhus fever with para-aminobenzoic acid.

The possible therapeutic value of para-aminobenzoic acid was suggested by Snyder, Maier and Anderson,² who reported that the mortality of experimental murine typhus in white mice was reduced by the oral administration of the drug. In their experiments approximately 80 per cent of the untreated control mice died of murine typhus after intraperitoneal inoculation of infected yolk sac suspensions (Wilmington strain),³ whereas more than four fifths of the mice which were

fed on a ration containing para-aminobenzoic acid survived the same infecting dose of yolk sac. Even when the oral administration of para-aminobenzoic acid was started one or two days after the inoculation of rickettsias, there was a difference between the treated and the control groups.⁴ Although large amounts of para-aminobenzoic acid were required to demonstrate this effect, the results were sufficiently encouraging to stimulate the clinical trial of the drug, which has been undertaken in the United States of America Typhus Commission ward at the Fever Hospital, Cairo, Egypt.⁵ After the clinical study was in progress we received other reports which extended the observations of the effect of para-aminobenzoic acid in experimental typhus. Andrewes, King and van den Ende,⁶ in testing a large number of compounds, observed a slight effect when maximal doses of para-aminobenzoic acid were given to mice infected by the intranasal route. Hamilton, Plotz and Smadel⁷ noted a definite inhibitory effect of high concentrations of para-aminobenzoic acid on the growth of typhus rickettsias in the yolk sac membrane of developing chick embryos. The results of the experimental work cited are in agreement with the clinical observations which form the basis of this report.

CLINICAL STUDY OF TYPHUS FEVER IN EGYPT

Through the courtesy of the Egyptian officials, the United States of America Typhus Commission established an experimental ward in the Cairo Fever Hospital early in 1943, at the beginning of one of the most severe epidemics of typhus which Egypt has experienced. More than 2,000 cases were admitted to the Fever Hospital in May 1943 at the peak of the outbreak. Although the epidemic was less extensive in 1944, there was an excellent opportunity throughout both seasons to study the clinical aspects of the disease.

In order to provide a background for the evaluation of para-aminobenzoic acid therapy, the experience with louse borne typhus cases in 1943 and 1944 is reviewed briefly. All the cases discussed in this report were considered to be certain cases of typhus fever on the basis of clinical evidence. The diagnosis in nearly every instance was supported by definite laboratory results (rise in titer of Weil-Felix and complement fixation tests). In some cases the direct isolation of rickettsias was successful either from blood or from lice fed on the patients during the febrile period. All the strains which have been isolated from patients in the Commission ward have exhibited the characteristics of typical louse borne typhus both in 1943⁸ and in 1944.⁹

During the two seasons, 159 patients with typhus were admitted to the Commission ward. Of this number there were 44 patients who may be compared with the cases in the treated series, in that they were unvaccinated Egyptian males between the ages of 18 and 48, who entered the ward before the end of the seventh day of illness. They received no therapy other than nursing

From the United States of America Typhus Commission Unit at the Fever Hospital, Cairo, Egypt.

Lieutenant Colonel Snyder is a member of the staff of the International Health Division of the Rockefeller Foundation, on leave.

The supplies of para-aminobenzoic acid were made available by the International Health Division of the Rockefeller Foundation and Dr. Herald R. Cox (Lederle Laboratories).

The authors received generous cooperation from the officials of the Egyptian Ministry of Public Health, who facilitated the studies of the United States of America Typhus Commission in Egypt.

The director of the Cairo Fever Hospital, Dr. M. A. B. Demerdash Bey, made possible the establishment of the United States of America Typhus Commission ward and laboratory in his institution. His extensive experience with typhus, his continued interest in the work and his helpful advice and cooperation were of the greatest value.

In 1943 numerous chemical determinations for the cases in this study were performed by the 35th General Hospital laboratory staff.

In 1943 most of the serologic tests for the commission ward were performed by Col. Harry Plotz, M. C., A. U. S., and Capt. B. L. Bennett, Sn. C., A. U. S., with the technical assistance of Sergeant Gunn.

Technical assistance was given by Sergeants Stephens and Dworakowicz and Corporals Stearnman, Horan, Cassell and Friedberg in the laboratory work of the commission ward.

care, fluids and appropriate measures to combat specific complications which occurred during the course of hospitalization. This group of patients is designated as the "untreated" group.

ESTIMATION OF THE SEVERITY OF ILLNESS

After discharge from the hospital each patient was classified on the basis of his clinical course. The principal factors which influenced the estimation of severity were the intensity of subjective symptoms (headache, generalized bodily aches and pains, tinnitus, deafness), the degree of prostration, the extent of central nervous system involvement (mental dulness, stupor, coma, incontinence of urine and feces, abnormal neurologic signs), the severity of cardiovascular system involvement (hypotension, tachycardia, peripheral vascular failure, myocardial damage) and finally occurrence of urinary retention, oliguria, nitrogen retention, bronchopneumonia, otitis media, parotitis, furunculosis and gangrene. With these factors in mind the following classification was made:

B. Cases with minimal symptoms and signs, yet definitely diagnosed as typhus on clinical evidence.

C. Cases of moderate severity, showing slight prostration, central nervous system involvement, cardiovascular changes or mild complications.

TABLE 1.—Forty-Four "Untreated" Cases of Typhus Classified According to Clinical Severity*

Number and Percentage of Cases in Each Classification				
B	C	D	E	F
1 (2%)	12 (27%)	18 (41%)	5 (11%)	8 (18%)

* Unvaccinated Egyptian males, aged 18-48 inclusive, admitted to the ward in the first week of illness. The criteria of classification are described in the text. This footnote applies also to tables 2, 3, 4 and 6.

D. Severe typhus cases with pronounced prostration, central nervous system involvement, cardiovascular changes or serious complications.

E. Cases of such severe illness that a fatal outcome was expected at some point in the clinical course.

F. Fatal cases.

SEVERITY OF "UNTREATED" TYPHUS FEVER

The classification of the 44 "untreated" cases is shown in table 1. One case was B, 12 were C, 18 were D, 5 were E and 8 were F. This distribution of severity in the 44 "untreated" cases was parallel with that encountered in the entire experience of our ward as regards unvaccinated "untreated" patients in the same age group, irrespective of the day of illness at the time of admission to the ward. The rarity of mild cases is noteworthy.

TREATMENT WITH PARA-AMINO BENZOIC ACID

Twenty cases of typhus were treated with sufficiently large amounts of para-aminobenzoic acid to produce a measurable concentration of the substance in the blood. Before arrangements were made to determine blood levels of para-aminobenzoic acid, 3 patients were given small doses which are considered as entirely inadequate in the light of subsequent studies. Those cases are not included in this report. The treated cases are considered in three groups:

Group 1. Controlled series: 10 patients received para-aminobenzoic acid while the alternate patients were given routine ward care only.

Group 2. Consecutive series: 7 patients were treated with para-aminobenzoic acid; no alternate control cases were included.

Group 3. Miscellaneous cases: a group composed of 2 patients who had been ill with typhus longer than seven days at the time treatment was begun and 1 patient, aged 70, who received para-aminobenzoic acid in the third twenty-four hours of his illness.

Selection of Patients.—The patients selected for the controlled series and the consecutive series (groups 1 and 2) were unvaccinated males between 18 and 48 years of age, who had no obvious complicating conditions at the time of admission, whose date of onset of illness was clear and who were not later in their disease than the seventh twenty-four hours.¹⁰

Fifth and sixth day cases were accepted in the study group only if it was possible to make a clinical diagnosis of typhus at the time of inclusion in the series. Earlier cases were accepted without a positive clinical diagnosis at the time of admission if relatives or close personal contacts were known to have had typhus recently. Four cases were obtained from a group of family contacts who reported to the ward daily; their onset of illness actually occurred while they were under observation.

In the controlled series the decision as to which patients would receive para-aminobenzoic acid was made automatically. Alternate patients were treated in the order in which they entered the hospital. Two exceptions to this rule occurred. The series was interrupted by error when 2 patients were treated consecutively and by arbitrary decision when a man whose wife and father both died of typhus was treated with para-aminobenzoic acid although the series required a control (case 6921).

Plan of Treatment.—In all instances para-aminobenzoic acid was administered by mouth. The initial dose varied from 4 to 8 Gm. In the majority of cases the initial dose was followed by 2 Gm. every two hours unless the concentration in the blood attained excessive values. Adjustments in dosage were made in relation to fluid intake and urinary output. The fluid intake in nearly all instances was adequate to maintain the output of urine between 1,500 and 3,000 cc. in twenty-four hours.

The effort was made to keep the concentration of para-aminobenzoic acid in the blood between 10 and 20 mg. per hundred cubic centimeters. Para-aminobenzoic acid is absorbed and excreted very rapidly, so that a two hourly schedule of administration was decided on as that most likely to produce a relatively constant blood level. Determinations made at various times during treatment indicated that the two hourly schedule was effective in maintaining a satisfactory concentration of para-aminobenzoic acid throughout the period of therapy.

Para-aminobenzoic acid was continued for varying lengths of time in the first cases. Subsequently it was decided that treatment should be continued until the patient's rectal temperature was 37.5 C. (99.5 F.) or less for twenty-four hours. The average amount of

10. The study was restricted to cases in the first week of illness for two principal reasons. The response to para-aminobenzoic acid in the first few cases was not apparent for several days. There was no abrupt, dramatic change such as that produced by sulfonamide drugs in pneumococcal pneumonia, for example. It seemed unlikely that late cases could be treated with any prospect of evaluation of results unless a very much larger group of cases could be observed than the admission ward would accommodate. Furthermore, the great majority of cases in an epidemic can be diagnosed by the end of the seventh day. This time was arbitrarily chosen, therefore, as the basis of selection of cases.

para-aminobenzoic acid for each case (groups 1 and 2) was approximately 127 Gm. The patients who are the subject of discussion in this study received para-aminobenzoic acid for at least three days.

Nausea and vomiting attributable to para-aminobenzoic acid occurred in the first few cases. Thereafter, in order to lessen gastric irritation, sufficient sodium bicarbonate was given to neutralize the para-aminobenzoic acid. The acidity of the urine was determined at least once daily during para-aminobenzoic acid therapy. The amount of sodium bicarbonate was varied as required to keep the urine approximately neutral in reaction. After this plan was adopted, vomiting was encountered very infrequently.

Para-aminobenzoic acid was available in tablets of 0.5 Gm. each and in capsules of 0.3 Gm. each. Neither form was suitable for administration to typhus patients, who could not be persuaded to swallow the large number of tablets or capsules required for each dose; but they took powdered para-aminobenzoic acid readily if it was suspended in water or partially dissolved in a sufficient volume of 5 per cent sodium bicarbonate solution to render the mixture slightly alkaline. The usual amount was 2 Gm. of powdered para-aminobenzoic acid with 25 cc. of sodium bicarbonate solution. After swallowing the mixture, the patient was quickly

TABLE 2.—Comparison of the Clinical Severity of Nine "Untreated" Control Cases and Ten Cases Treated with Para-Aminobenzoic Acid in Group 1

	Number and Percentage of Patients in Each Classification				
	B	C	D	E	F
"Untreated" control cases.....	0	1 (11%)	2 (22%)	1 (11%)	4 (44%)
Cases treated with para-aminobenzoic acid.....	8 (80%)	1 (10%)	1 (10%)	0	0

given water to take away the slightly unpleasant taste of the drug. This method of administration was entirely satisfactory in most instances. Two patients, however, took their initial doses with difficulty, and no further attempt was made to treat them because of their uncooperative attitude. They have not been included in this report.

Method of Determination of Para-Aminobenzoic Acid in the Blood.—The blood levels refer to free para-aminobenzoic acid as determined by Marshall's and Litchfield's procedure for sulfanilamide.¹¹ The standard solution of sulfanilamide was replaced by a standard of para-aminobenzoic acid. For some of the tests a Duboscq colorimeter was used; for the majority, however, a Coleman spectrophotometer was employed.

The Results of Treatment with Para-Aminobenzoic Acid.—In group 1, of the 10 patients who received para-aminobenzoic acid, 8 were classified as B cases, 1 was C and 1 was D. Of the 9 alternate control cases, 1 was C, 3 were D, 1 was E and 4 were F (table 2). The temperature charts of the patients in group 1 are shown in charts 1 and 2. All temperatures were taken rectally, with a single exception, patient 5768, chart 2, the values for the nineteenth day to the twenty-fourth day indicating oral temperatures. The solid line beneath the temperature curve shows the period of administration of para-aminobenzoic acid.

Group 2. The results of this consecutive series are similar to those in group 1. Of 7 cases 3 were B, 3 were C and 1 was D. Temperature curves are shown in chart 3. The temperature curve of a typical untreated case (12412) appears at the top of chart 2 for comparison with the para-aminobenzoic acid cases.

The 17 cases in groups 1 and 2 are contrasted with the 44 "untreated" cases in table 3, which shows the incidence of clinical severity in the two groups.

Group 3. Two patients in this group were treated for the purpose of extending the experience with para-aminobenzoic acid to patients admitted in the eighth and ninth day of illness. One patient, 6546, was started

Chart 1.—Group 1 controls. Temperature charts of 9 "untreated" control typhus patients, arranged according to the day of illness at the time of admission to the hospital. The clinical classification of severity appears at the end of the fever curve. Values indicate rectal temperature in degrees centigrade. The numbers across the top of the chart refer to the day of illness. The hospital number and age of the patient appear at the beginning of each temperature curve.

on para-aminobenzoic acid in his ninth day. He became progressively worse and died on the thirteenth day.

Patient 7,100, admitted at the end of his eighth day of illness, was severely dehydrated. His urine contained many red cells on admission, but these disappeared in the next two days. The clinical course was complicated by a secondary rise in temperature associated with pain in the right flank, which may have been related to previous renal or ureteral disease.

Finally, patient 6,811, a man aged 70, was given para-aminobenzoic acid in the third twenty-four hours of

11. Marshall and Litchfield, quoted from technical manual Methods for Laboratory Technicians, War Department, Oct. 17, 1941, p. 134.

his illness to ascertain whether para-aminobenzoic acid would affect the outcome. The patient died on the eleventh day; aspiration of para-aminobenzoic acid and sodium bicarbonate may have contributed to the death of this patient. His case is discussed later. Temperature curves are shown in chart 4.

The pathology of the 2 fatal cases in this group will be described in a later United States of America Typhus Commission report by Lieut. Comdr. W. B. McAllister Jr. (MC), U.S.N.R.

The experience with para-aminobenzoic acid is summarized in tables 4 and 5, which show the clinical

Chart 2.—Group 1 para-aminobenzoic acid cases. Temperature charts of 10 typhus patients who received para-aminobenzoic acid, arranged according to day of illness at the time para-aminobenzoic acid was started. The period of administration of para-aminobenzoic acid is indicated by the heavy line beneath the temperature curve. The clinical classification of severity appears at the end of the fever curve. The numbers across the top of the chart refer to the day of illness. The hospital number and age of the patient appear at the beginning of each temperature curve.

severity, duration of fever, total amount of para-aminobenzoic acid, complications and laboratory data.

Effect of Para-Aminobenzoic Acid on the Rash of Typhus.—Fifteen patients who received para-aminobenzoic acid had a definite rash, which was not as extensive, however, as that seen in the majority of "untreated" patients. The rash was considered to be questionable in 3 treated patients (4622, 14868 and

15080). No rash was seen at any time in 2 of the treated patients whose skins were very dark (5247 and 15000).

It was interesting to note that 2 patients who were treated in the second and third day of illness nevertheless developed a rash which was distinctive of louse borne typhus in every particular except that the lesions were relatively few in number and tended to disappear quickly.

Effect of Para-Aminobenzoic Acid on the White Blood Cells.—One patient, not tabulated in the series, developed a low white blood cell count (2,900) after twenty-four hours of treatment, and para-aminobenzoic acid therapy was discontinued. One other patient, 6540, likewise developed a low white blood cell count (2,950) but in his case the low count did not occur

* A rectal temperature above 37.5 C. (99.5 F.) is considered as evidence of fever.

until he had been afebrile for two days. Para-aminobenzoic acid had been discontinued twenty-four hours before the low value was obtained. The count fell further to 1,850 and rose thereafter to 3,500 at the time of discharge. The return of the white blood cell count toward normal values was slow in both patients, but neither one showed any other evidence of untoward drug reaction, and both had a mild, uncomplicated course. The differential count did not reveal any significant alteration in the relative percentages of polymorphonuclear leukocytes and lymphocytes. In the other para-aminobenzoic acid cases a tendency for the white blood cell count to drop to values between 5,000 and 3,500 was observed.

Effect of Para-Aminobenzoic Acid on Red Blood Cells and Hemoglobin.—No changes in red cell count or hemoglobin estimation were encountered in the para-aminobenzoic acid cases that were not consistent with typhus.

Effect of Para-Aminobenzoic Acid on Kidney Function.—There was no evidence in any of the para-aminobenzoic acid cases that the drug had produced renal complications. Indeed the low incidence of nitrogen retention¹² (12 per cent) in the treated cases (groups 1 and 2) as contrasted to that in the "untreated" cases (44 per cent) suggests that para-aminobenzoic acid may prevent renal damage in typhus. This subject receives further consideration in the comment.

Secondary Rise in Temperature.—In 9 cases, after the temperature had declined either to normal or at least to a point definitely below the expected value for typhus cases, para-aminobenzoic acid was discontinued.

A secondary rise in temperature was then observed, varying from minimal brief elevations above normal to moderately high fever of several days' duration. When this phenomenon was first encountered, several explanations were considered: (a) that it represented a recurrence of typhus; that is to say, a release phenomenon related to the premature withdrawal of the inhibitory effect of para-aminobenzoic acid on the typhus rickettsias; (b) that there might be complicating infections; (c) that the fever was attributable to para-aminobenzoic acid alone. After careful survey of all

Importance of Early Treatment.—The best results were obtained when para-aminobenzoic acid was started on the second and third days of illness. Some effect was noted when treatment was begun as late as the seventh day. In this study the only ninth day patient who was treated, 6546, died on the thirteenth day despite large doses of para-aminobenzoic acid. It is clear that a very much more extensive experience with para-aminobenzoic acid would be required to define the limits within which beneficial results might be expected. The importance of early treatment is quite obvious, however.

Chart 3.—Group 3 para aminobenzoic acid cases. Temperature charts of 3 typhus patients who received para aminobenzoic acid. Other details are explained in the description of chart 2.

the information available, it seems likely that the secondary rise was a manifestation of typhus, as postulated in a. Unfortunately this point was not investigated by inoculation of animals with blood taken during the secondary febrile period. One patient, 5768, had an exacerbation of chronic amebic dysentery, which offers a possible explanation of the secondary fever, although the latter did not closely coincide with the onset of diarrhea.

The high incidence of secondary febrile periods raises the question whether therapy was adequate in amount and duration. The patients who developed the secondary fever might have had such a widespread dissemination of rickettsias that they would have been D, E or F cases if untreated and might have required longer, more intensive treatment with para-aminobenzoic acid for elimination of the secondary rise in temperature.

A striking feature of the secondary febrile period was the paucity of symptoms and signs of typhus of a degree comparable to the height of the temperature. Mild headache and slight anorexia were the only constant complaints.

Chart 4.—Group 2 para aminobenzoic acid cases. Temperature charts of 7 cases of typhus treated with para aminobenzoic acid consecutively without alternate control cases. A typical fever chart of an untreated patient, 12412, appears at the top of the chart for comparison with the treated cases. Other details are explained in the description of chart 2.

Influence of Age on Results Obtained with Para-Aminobenzoic Acid.—Only 1 patient was given para-aminobenzoic acid who was outside the 18 to 48 age group. This patient was 70 years old, and treatment was started on the third day of illness. Although he received a large amount of para-aminobenzoic acid, the patient died. His case is discussed later.

Within the 18 to 48 age group, among the cases treated before the end of the seventh day of illness, the increase in age is not associated with increase in severity of illness. In the treated series the average age in the B cases is 29 years, C cases 27 years and

12. Blood nonprotein nitrogen values of 45 mg. per hundred cubic centimeters or higher are interpreted as evidence of nitrogen retention. Among the 44 "untreated" cases, blood nonprotein nitrogen determinations were made in 32 cases. Of these 14, or 44 per cent, were greater than 45 mg. per hundred cubic centimeters at some period in the course of the illness.

D cases 26 years. In the "untreated" series the average age in C and D cases is 25 years, in E cases 26 years and in F cases 33 years. Table 6 shows the relation of average age to clinical severity for both groups.

Contraindications to Para-Aminobenzoic Acid Therapy.—A white blood cell count below 3,000 has been regarded as a definite contraindication to further para-aminobenzoic acid therapy. Since there was a general tendency toward leukopenia, and since 2 patients had counts below 3,000, it is important to obtain daily white blood cell counts during the administration of para-aminobenzoic acid.

In the presence of severe dehydration and oliguria the usual plan of treatment (initial dose of 4 to 8 Gm.

In 3 instances very high concentrations of para-aminobenzoic acid in the blood were encountered. The maximum value in the series was 49 mg. per hundred cubic centimeters. One patient became very drowsy and disoriented when his blood level was approximately 40 mg. per hundred cubic centimeters. Another patient became delirious when his blood level was 35 mg. per hundred cubic centimeters. Although these findings could be ascribed solely to typhus, nevertheless they were regarded as toxic manifestations of para-aminobenzoic acid because they promptly disappeared when the blood level fell to a low value.

If a patient is too weak or stuporous to swallow properly, the administration of para-aminobenzoic acid

least to 1,500 cc. in twenty-four hours, the schedule of dosage should be modified according to the values obtained by frequent determinations of the blood level.

by mouth should not be attempted, since there is the possible danger of severe tracheitis from aspiration of the drug. One patient, 6811, aged 70, became so prostrated that he was unable to swallow rapidly. As a consequence of overzealous nursing he probably aspirated a fairly large amount of para-aminobenzoic acid and sodium bicarbonate. Oral therapy was discontinued as soon as this was discovered and penicillin was administered, but the patient died twenty-four hours later. At autopsy there was a minimal amount of pneumonitis; the principal finding was intense tracheitis and bronchitis, which was attributed largely to the aspiration of para-aminobenzoic acid and sodium bicarbonate. Although a stomach tube was not employed for the administration of para-aminobenzoic acid in the cases in this series, it is possible that the severe tracheitis of patient 6811 might have been avoided if a tube had been passed when difficulty in swallowing first developed.

Early in the experience with para-aminobenzoic acid it was considered that the presence or the development of a bacterial infection might constitute a contraindication to para-aminobenzoic acid therapy. For example, treatment with para-aminobenzoic acid was terminated in patient 15564 when he developed suppurative ophthalmia as a complication of late stage trachoma. It is not possible, however, to conclude that bacterial infections actually constitute a contraindication to para-aminobenzoic acid on the basis of the experience gained from the observation of the 20 cases in this study. At the present time the view is held that para-aminobenzoic acid probably should be continued in cases of typhus despite the occurrence of secondary bacterial infections.

The Use of Penicillin for the Treatment of Typhus Complicated by Bacterial Infections.—If organisms susceptible to the action of penicillin are encountered in secondary bacterial infections which may complicate typhus, the use of penicillin to supplement but not to replace para-aminobenzoic acid therapy is recommended rather than sulfonamide drugs for several reasons: (a) Sulfonamide drugs in experimental typhus seem to have a deleterious effect;² (b) para-aminobenzoic acid inhibits the action of sulfonamide drugs on bacteria in vitro, a fact which prompts the prediction that sulfonamide drugs would be ineffective against secondary bacterial infections when administered in the presence of a high blood concentration of para-aminobenzoic acid; (c) penicillin has been found to exert a beneficial effect in experimental typhus by Pinkerton and his co-workers, both in mice and in the infected yolk sacs of developing chick embryos.¹² Clinical trial of penicillin primarily for the treatment of louse borne typhus in the Commission ward has been attempted in 4 cases. It is not possible to decide on the basis of such a limited experience whether penicillin, given early and in large amounts, does or does not affect the course of typhus itself. Nevertheless, by reducing or eliminating bacterial infections penicillin may offer considerable help to a seriously ill patient who would not otherwise survive the extra burden of a bacterial infection superimposed on that of typhus.

Optimum Dosage of Para-Aminobenzoic Acid.—At this time it is not possible to draw any conclusions as to the optimum dosage of para-aminobenzoic acid. It can be stated on the basis of this study that the patients who received the arbitrarily chosen dosage had relatively mild typhus. Whether the amount of para-aminobenzoic acid was excessive or minimal is not known.

COMMENT

The experience through two seasons in Egypt has clearly shown the very low incidence of mild cases of typhus in the "untreated" Egyptian patients in the 18 to 48 age group who were admitted to the Fever Hospital. Only 1 such case was encountered among 44 "untreated" patients in the Commission ward, whereas fatal cases were 18 per cent of the total. By contrast, it was very striking to find 11 mild or B cases in the same group when para-aminobenzoic acid was given before the end of the seventh day of illness among 17

patients, none of whom died. At the time the patients in group 1 were being studied, the mortality from typhus among the unvaccinated male patients aged 18 to 48 inclusive in the general wards of the Fever Hospital was 30, per cent. Furthermore, there were four deaths among 9 "untreated" cases of group 1 in the Commission ward. There can be no question that the typhus which prevailed during the period covered by this study was very severe. The high incidence of mild cases in the treated groups was therefore all the more impressive.

The length of time between the onset of illness and discharge from the hospital provides another demonstration of the difference in severity of illness between "untreated" cases and para-aminobenzoic acid cases (groups 1 and 2). For the "untreated" group the average was thirty-two days, for the para-aminobenzoic acid cases only twenty-one days. The figures do not include fatal cases.

Close daily observation of the patients convinced us, more than scrutiny of fever curves or tabulations of frequency of complications, that para-aminobenzoic acid lessened the severity of typhus. The treated patients developed few of the troublesome complications which make typhus cases so difficult for the nursing staff. The low incidence of prostration, stupor, coma, fall in blood pressure, urinary retention, oliguria, nitrogen retention and incontinence of urine and feces, which are so prominent in the untreated cases, was particularly impressive from the clinical point of view.

The drug appears to be quite safe for human administration. High blood levels (up to 49 mg. per hundred cubic centimeters) were accompanied by minimal constitutional effects. No detectable impairment of kidney function attributable to para-aminobenzoic acid was encountered in any of the cases. That typhus frequently produced severe impairment of renal function was a characteristic observation in the experience of the Commission ward. Therefore, any agent which might augment the tendency of typhus to produce oliguria and nitrogen retention is to be regarded with great suspicion. The absence of any undesirable effect of para-aminobenzoic acid on kidney function in this series is a very reassuring finding.

We wish to emphasize our conviction that a careful daily record of the fluid intake and urinary output is necessary in the care of the typhus patient. In our experience nitrogen retention, with or without oliguria, is the most serious development which may occur in typhus from the prognostic point of view. Without exception the fatal cases of typhus in which the blood chemistry was studied by the Commission, whether in the Commission ward or in the general wards of the Fever Hospital, showed a pronounced elevation of non-protein nitrogen. Forty-four per cent of the "untreated" cases in the Commission study, despite the vigorous administration of fluids (4 to 5 liters daily), exhibited some elevation of nonprotein nitrogen in the blood. Daily examination of the urine, continuous observation of the fluid intake, the output and specific gravity of the urine, as well as determinations of the blood non-protein nitrogen, plasma proteins, hematocrit and urea clearance, aid in the evaluation of renal insufficiency in typhus. This subject will be treated in greater detail in a later report of the United States of America Typhus Commission.

Speculations on the Mode of Action of Para-Aminobenzoic Acid.—The rickettsias of typhus are known to multiply inside the endothelial cells of small blood vessels. It is in these cells that they have been demonstrated in tissues from human autopsies.¹⁴ Multiplication of rickettsias outside living cells has not been proved. In one experiment the direct exposure of rickettsias to a concentration of 50 mg. of para-aminobenzoic acid per hundred cubic centimeters for one hour at 38 C. (100.4 F.) had no effect on their virulence for animals.¹⁵ This suggests that para-aminobenzoic acid does not act directly on rickettsias. The clinical data are consistent with this observation. The treated cases did not show a rapid improvement following the administration of para-aminobenzoic acid. The usual finding was that the progress of the disease was arrested and that the patients did not become appreciably sicker than they were at the time treatment was instituted. In the course of four to six days the temperature fell and considerable improvement in condition was apparent, as though the natural defenses of the body had finally disposed of the rickettsias. The hypothesis which best fits this sequence of events is that para-aminobenzoic acid inhibits the multiplication of rickettsias inside the cells, thereby permitting the immunity mechanisms of the body to dispose of them, whereupon the vascular lesions begin to heal. If para-aminobenzoic acid is withdrawn before the immunity mechanisms have finally disposed of the rickettsias, these latent, previously inhibited organisms may then resume their growth and cause an increase in size of the lesions or even the formation of new lesions. The secondary febrile periods which occurred in half the para-aminobenzoic acid treated cases may be explained on the basis of this hypothesis. The usual finding, that the rash of treated cases was less extensive, likewise supports the "inhibition hypothesis." However, it should be noted that in 2 cases a definite rash appeared despite the fact that para-aminobenzoic acid was given very early in the course of the disease. This is regarded as evidence that para-aminobenzoic acid did not completely inhibit the progression of lesions which had already been established.

Para-aminobenzoic acid plays a most important role in the metabolism of many micro-organisms which ordinarily multiply outside the cells of the body. The inhibitory effect of para-aminobenzoic acid on the growth of rickettsias, which are obligate intracellular organisms, opens a wide field for speculation on the metabolism not only of rickettsias but of other intracellular micro-organisms as well. Perhaps para-aminobenzoic acid alters an intracellular enzyme system in such a way as to render the cytoplasm unsuitable for multiplication, possibly by blocking the formation of an essential metabolite which rickettsias are unable to synthesize for themselves.

It is also possible that the action of para-aminobenzoic acid is related to the mechanisms by which rickettsial toxic substances are combated. In this regard it may be pointed out that the patients who received para-aminobenzoic acid did not have the usual degree of prostration and "toxicity" which are part of the picture of typhus. Moreover, such a hypothesis may offer an explanation of the very low incidence, in the treated

cases, of impairment of renal function, the importance of which is stressed elsewhere in this communication. For the purpose of our speculations we may postulate a hypothetical effect of rickettsial toxic substances on the kidney, resulting in impairment of renal function. If para-aminobenzoic acid plays a role in the detoxification mechanisms, this may explain the low incidence of nitrogen retention in the treated cases as contrasted to the high incidence in the "untreated" cases. However, there are other obvious considerations which are probably important in the development of the renal insufficiency in typhus; for example actual lesions in the kidney, severe hypotension and dehydration.

The material which is available for analysis does not permit the selection of a single hypothesis to explain our observations on the effect of para-aminobenzoic acid in typhus. Obviously a great deal of work is indicated on the problem of the mode of action of para-aminobenzoic acid.

The results of this study provide other subjects for speculation. Can compounds closely related to para-aminobenzoic acid be found which are even more effective? What is the scope of usefulness of para-aminobenzoic acid therapy in the face of an outbreak of typhus? What is the optimum dosage and plan of administration? What untoward reactions and complications may be expected? Will the course of other rickettsial diseases of man be favorably affected by para-aminobenzoic acid or closely related substances?

SUMMARY AND CONCLUSIONS

Twenty cases of louse borne typhus have been treated with para-aminobenzoic acid. Their clinical course has been compared with that of 44 "untreated" cases. The data from this study show that:

1. Large amounts of para-aminobenzoic acid were administered with ease to patients suffering from typhus.
2. There were no unfavorable effects when para-aminobenzoic acid was properly administered with the exception of a tendency to develop a low white blood cell count.
3. When treatment was started in the first week of illness, the clinical course of the patients who received para-aminobenzoic acid was much less severe than that of the "untreated" patients. The average duration of fever was considerably shorter in the treated group.

It is concluded that large doses of para-aminobenzoic acid exert a definite beneficial effect on the course of louse borne typhus if treatment is started in the first week of illness.

Cosmic Doctrine of Aristotle.—The cosmic doctrine of Aristotle holds that the world is a living being having a soul. Since everything created is for some particular purpose, the body of man is evolved as the habitat of the soul. Matter is composed of five elements, earth, air, water, fire and ether. Every element must be looked on as living, since it is pervaded by the soul of the universe; there is an unbroken chain from the simple elements through plant and animal up to man, the different groups merging by insensible shades into one another; plants are inferior to animals inasmuch as they do not possess a single principle of life or soul but many subordinate ones, as is shown by the circumstance that when they are cut to pieces each piece is capable of independent growth or life—Gordon, Benjamin Lee: *The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

GEORGE C. MEDAIRDY, M.D.
GERTRUDE FLEISCHMANN, M.D.
AND
L. EMMETT HOLT Jr, M.D.
BALTIMORE

It is clearly established that micro-organisms present in the rumen of ruminant animals will synthesize riboflavin in quantities sufficient to supply the requirements for this factor.¹ Biosynthesis of riboflavin has also been demonstrated in the cecum of the rat,² but in this omnivorous animal the phenomenon is conditioned by the diet, and only under particular conditions is it sufficient to furnish the requirements. Although it seems reasonably clear that riboflavin deficiency does occur in man, it is by no means clear that it always develops whenever the diet is deficient in riboflavin. The possibility that under given dietary conditions the intestinal bacteria of man might synthesize riboflavin, providing protection against deficiency, has never been evaluated. It is our purpose in the present report to describe experiments which demonstrate clearly the biosynthesis of riboflavin in the human intestinal tract—and in considerable quantities.

EXPERIMENTAL

Observations were made on 12 experimental subjects. These individuals were male adolescent youths between 10 and 16 years of age. After a control period on the institutional diet the subjects were placed on an experimental diet consisting of vitamin free casein, crisco, dextrimaltose, a mineral mixture³ and a vitamin mixture⁴ which contained no riboflavin. This diet provided 40 calories per kilogram, distributed approximately as follows: protein 15 per cent, fat 35 per cent and carbohydrate 50 per cent. The food, except for the vitamin mixture, was mixed together and given in equal portions at each meal. The vitamin mixture, given separately, was also supplied in equal quantities at each meal. Each of the food constituents was carefully assayed for riboflavin, but appreciable quantities of this factor were found to be present only in the vitamin free casein, which was found to contain 0.75-1.0 microgram per gram, providing an intake between 70 and 90 micrograms per day in the different subjects. The subjects pursued a sedentary life throughout the experiment. Complete fecal collections were made, which were analyzed for riboflavin in weekly periods. The urinary excretion of riboflavin was followed daily

in the fasting hour specimen,⁵ and complete twenty-four hour excretions were studied periodically. Analyses of riboflavin were made by the fluorometric method of Najjar,⁶ which was modified slightly for the assay of feces.⁷

RESULTS

The subjects remained in excellent health throughout the period of study (three months) with the exception of 1 individual, who developed a Vincent's stomatitis during the second week. This intercurrent infection can hardly be related to the experimental diet, since it cleared without the administration of riboflavin.

The urinary excretion of riboflavin fell during the first two weeks of the study but remained constant

thereafter, its level being of the order of magnitude of 6 to 10 micrograms in the fasting hour and 150 and 250 micrograms per day. The excretion of riboflavin in the feces showed no tendency to fall as a result of the riboflavin deficient diet, remaining at levels similar to those observed in the control period (200 to 600 micrograms per day). It was thus apparent that the combined excreta contained five to six times as much

7. Fresh stools mixed with glacial acetic acid (10 cc for each hundred grams) were collected in glass jars. These were protected from light by black paper wrapping and kept in a refrigerator before analysis. Two grams of wet stool was mixed with 20 cc. of fifth molar acetate buffer (pH 4.5) and allowed to stand over a steam bath with frequent stirring for twenty minutes. The resulting mixture was then centrifuged and the sediment extracted with 10 cc. of buffer for ten minutes and likewise centrifuged. The two supernatant fluids were pooled and a 5 cc. aliquot taken for the determination of the riboflavin in the same manner described for urine.

From the Department of Pediatrics, Johns Hopkins University School of Medicine, and the Department of Mental Hygiene, State of Maryland. This study was supported in part by a grant received from Mead Johnson and Company, the "Cox" Mineral Mixture, and the Williams Waterman Fund for the Study of Vitamin Deficiencies.

3. The Cox Mineral Mixture was employed, *Proc Soc Exper Biol Med* 34: 443, 1936.
4. The vitamin mixture, which supplied the following water soluble factors, was divided into three equal doses which yielded the following daily quantities: ascorbic acid 25 mg., nicotinamide 25 mg., calcium pantothenate 1 mg., pyridoxine 1 mg., choline chloride 5 mg., inositol 1 mg., para-aminobenzoic acid 1 mg., and thiamine 1 mg. In addition 5 drops of Mead Johnson cod liver oil concentrate were given daily. The water soluble vitamins were supplied through the courtesy of Merck & Co., Inc.

riboflavin as was ingested in the food, a phenomenon which could be explained only by the production of riboflavin by the intestinal bacteria. The remote possibility that the stool riboflavin might represent excretion of body stores rather than intestinal synthesis was excluded by experiments on normal subjects in whom intravenous injections of 5 to 20 mg. caused no increase in fecal riboflavin. The fact that riboflavin could be absorbed from the large intestine was demonstrated by means of enemas containing 20 mg. of riboflavin, which brought about a prompt rise in the excretion of riboflavin in the urine.

Because of our observation that the administration of succinylsulfathiazole would inhibit the bacterial synthesis of thiamine in the human intestinal tract,⁸ the attempt was made to decrease the riboflavin synthesis by the administration of this drug. Succinylsulfathiazole was commenced during the seventh week of the study in doses of 1.5 Gm. every four hours. After the ninth week the dose was increased to 3 Gm. every four hours, which was continued until the termination of the study.

Although the administration of succinylsulfathiazole caused a virtually complete disappearance of thiamine from the stools in the course of a few days, very much to our surprise it produced relatively little effect on the output of riboflavin.⁹ None of the twelve subjects showed a reduced riboflavin output in the stools; in fact the daily excretion was, if anything, somewhat higher after the administration of the drug (table 1). Of the 12 subjects, 9 showed no reduction in the urine output, 2 showed a very temporary reduction and only 1, a subject who had previously been excreting quantities of riboflavin considerably greater than the rest, showed a reduction to levels comparable with the other subjects (table 2).

COMMENT

The great excess of riboflavin in the excreta of our subjects as compared with the intake, the fact that it continued without appreciable decrease for twelve weeks and that the subjects remained in excellent health all this time without any loss of weight, all support the view that under these conditions the intestinal bacteria can synthesize enough of this factor to supply the requirements of the individual for this period of time. Disregarding the quantity utilized or otherwise destroyed in the body, it appears that the riboflavin produced in the body was five or six times the intake and in some instances more than ten times the intake. The fact that succinylsulfathiazole failed to inhibit the synthesis of riboflavin to any significant degree suggests that this factor is produced by organisms which are not susceptible to the drug, although it may also be produced by those which are susceptible. Smears of the feces after the administration of the sulfonamide drug still showed an abundance of bacteria to be present, although detailed bacteriologic studies of the stools were not made.

Further studies are needed to find out whether a minute amount of riboflavin such as was present in our experimental diet is needed for the bacterial synthesis of this factor or whether such synthesis would occur in

any case. The conditions under which biosynthesis of riboflavin occurs in man likewise remain to be defined. We have no reason to doubt that under certain conditions riboflavin deficiency does occur in man, but the observations we have presented certainly cast doubt on the high and the universal requirement for this factor that has hitherto been accepted.

SUMMARY

1. Twelve experimental subjects, placed on an experimental diet of purified vitamin free foods, in which only supplements of pure vitamins were given, subsisted for a period of twelve weeks on a diet containing between 60 and 90 micrograms of riboflavin per day.

2. The excretion of riboflavin in the urine, after a preliminary drop, tended to remain constant at a value roughly twice that of riboflavin intake. The fecal excretion remained unaffected at a level of five to six times the intake, a phenomenon which can be attributed to synthesis of riboflavin by the intestinal bacteria.

3. An attempt to inhibit the biosynthesis of riboflavin by the intestinal bacteria by the administration of succinylsulfathiazole for a period of four weeks met with no success.

4. The conclusion is drawn that riboflavin may not be a dietary essential under all conditions. The conditions in which it may be effectively synthesized in the intestine remain to be defined.

Clinical Notes, Suggestions and New Instruments

FATAL AGRANULOCYTOSIS RESULTING FROM THIOURACIL

JULIUS KAHN, M.D., AND ROBERT P. STOCK, M.D.,
LOS ANGELES

Leukopenia and granulocytopenia have been reported as potential dangers in the use of thiouracil when given to thyrotoxic human beings. Similar observations have been made on adult rats which were fed thiourea.¹ Only 1 of the 72 patients in the group reported by Williams and Clute² developed agranulocytosis following the use of thiouracil, but this was not fatal. Astwood³ also discussed 1 nonfatal case in a man whose toxic diffuse goiter similarly was treated with thiouracil. The following, as far as can be determined, is the first death that can be attributed to thiouracil as an agranulocytogenic agent:

REPORT OF CASE

History.—M. M., a white woman aged 62, entered the Cedars of Lebanon Clinic Hospital on March 3, 1944 because of nausea, vomiting and drowsiness of six hours' duration. She had been known to have diabetes for six years and had been negligent both in taking insulin and in adhering to a prescribed diet. Diffuse goiter of relatively mild toxicity had been present for about ten years. In 1940 a course of therapy with Lugol's solution had resolved the thyrotoxic symptoms almost entirely. On this admission to the hospital the patient was in impending diabetic coma with a blood sugar of 450 mg. per hundred cubic centimeters. Her urine showed a strongly positive reaction to tests for acetone and diacetic acid and a 4 plus qualitative Benedict's reaction. Her blood pressure was 200 mm. of

From the Thyroid Committee of the Cedars of Lebanon Hospital. Dr. Kahn is chief of the medical service and Dr. Stock is resident in internal medicine.

9. The possibility that succinylsulfathiazole may interfere with the determination of riboflavin in the stools was ruled out. The drug is not fluorescent under the same optical conditions. Incubation of sterilized stools with added succinylsulfathiazole for two hours at 37 C. showed no change in the riboflavin content.

mercury systolic and 0 diastolic. The response to therapy directed against acidosis was prompt. However, because of the unstable nature of her diabetes, wholly satisfactory control never was possible. During the next two months the patient had a few insulin reactions of minor degree.

As soon as possible after the diabetic acidosis had been corrected, evaluation of the patient's thyrotoxicosis was undertaken and the patient then was placed under the supervision of the thyroid committee of the hospital. The thyroid gland was diffusely enlarged to a slight degree. Exophthalmos was slight, and a fine tremor of the hands was present. A labile pulse varied between 100 and 120 per minute. The basal metabolic rate on the eleventh hospital day was plus 65 per cent on two determinations. Blood cholesterol was 164 mg. per hundred cubic centimeters. A blood iodine test by the Chaney method was 13 (normal, 5 to 7) micrograms per hundred cubic centimeters of plasma. The body weight at that time was 77 pounds (35 Kg.). Blood studies showed the hemoglobin to be 13.7 Gm. per hundred cubic centimeters with an erythrocyte count of 3,970,000 per cubic millimeter. There were 5,100 leukocytes per cubic millimeter with 66 per cent neutrophils, 3 per cent eosinophils, 27 per cent lymphocytes and 4 per cent monocytes.

During this period the patient was feeling well and was consuming 2,500 calories (carbohydrate 200, protein 110, fat 140) daily. Each morning 26 units of crystalline zinc insulin and 34 units of protamine zinc insulin were administered. Because of the age of the patient and the instability of her diabetes, thiouracil was regarded as a desirable agent for managing her thyrotoxicosis.

Beginning April 18, thiouracil was started with an initial dose of 0.8 Gm. per day (in four divided doses) for two days. Thereafter the amount was decreased to 0.6 Gm. per day (in three divided doses). A complete blood count, determination of the basal metabolic rate, routine urinalysis and recordings of body weight were ordered every five days.

Favorable response to the thiouracil was prompt. The basal metabolic rate had dropped in fourteen days to plus 42 per cent, the patient had gained 4 pounds (1.8 Kg.) and the pulse was 80 per minute. Slight enlargement of the thyroid gland was noticed. The response to thiouracil continued to be favorable, with a gradual rise in body weight and progressive lowering of the basal metabolic rate.

On the forty-fourth day of medication with thiouracil the basal metabolic rate was plus 10 per cent, the weight 90 pounds (41 Kg.) and the pulse stable at 80 per minute. At this time the dosage of thiouracil was reduced to 0.4 Gm. per day.

Seven days later the patient suddenly complained of a "swollen, dry throat," and within twelve hours her temperature rose to 101.4 F. Except for moderate congestion of the pharynx, physical findings were unchanged. Next morning the temperature was 98.0 F. The throat was still reddened, and tender submaxillary nodes were palpable. Within twenty-four hours the temperature rose to 105 F. (rectally). Pronounced congestion and edema of the soft palate was present.

The erythrocyte count at this time was 3,650,000, but the leukocyte count had fallen to 1,100 per cubic millimeter, with 2 per cent neutrophils, 1 per cent eosinophils and 97 per cent lymphocytes. Thiouracil was stopped immediately. A throat culture showed a few colonies of *Streptococcus viridans* and a moderate number of colonies of *Staphylococcus aureus*. A transfusion of 500 cc. of whole blood was given promptly. On the next day the leukocyte count was 300 per cubic millimeter, with 1 per cent neutrophils and 99 per cent lymphocytes. The pharyngeal mucosa became more reddened, and numerous blebs were present. Erythematous macules were seen to be scattered widely over the body. Within the next twenty-four hours 1,500 cc. of whole blood was given by transfusion. Other attempts at combating the agranulocytosis included injections of crude liver extract (15 units twice daily), pentose nucleotide (10 cc. injected intramuscularly every four hours) and oral administration of extract of yellow bone marrow. As an added effort against the rapidly progressive infection, penicillin was

administered intramuscularly in doses of 20,000 units every two hours for four doses and then the same amount every three hours.

During the final two days of life the patient presented a profoundly stuporous picture somewhat similar to that caused by diabetes. The carbon dioxide combining power was 38 volumes per cent, and moderate glycosuria persisted. However, there was no acetoneuria, and the blood sugar varied between 56 and 142 mg. per hundred cubic centimeters.

Despite all therapy the coma persisted, the temperature remained high, the buccal and pharyngeal lesions grew worse, jaundice appeared, and the agranulocytosis persisted. The patient died June 14, five days after the appearance of agranulocytic angina.

A total of 30.8 Gm. of thiouracil had been given over a period of fifty-four days preceding the clinical development of agranulocytosis.

Autopsy.—The autopsy was performed by Dr. Rubin Strauss, pathologist of the Cedars of Lebanon Hospital, ten hours and thirty-five minutes after death. The significant findings were as follows:

There was extensive generalized jaundice, and a number of scattered red areas 2 to 7 mm. in diameter resembling petechiae were seen on the torso and extremities. Microscopically these showed hemorrhage and some bacterial masses but no appreciable leukocytic reaction. The buccal mucosa was covered with sordes. The soft palate and pharynx were hyperemic, moderately edematous and in places covered with sordes. No ulcerations were seen. Microscopically no polymorphonuclears were noted, but there was moderate infiltration by small round cells. The bone marrow of several ribs and bodies of vertebrae was abundant and dark red. Microscopically, the cells of the granulopoietic series appeared to be greatly reduced in number.

Except for moderate fibrosis of the mitral leaflets and regional chordae tendineae, the cardiovascular system presented no appreciable abnormality. The lungs were heavier than average chiefly because of congestion and edema. There were scattered areas of hemorrhage but no pneumonia. The spleen was slightly heavier than usual and showed nothing but moderate congestion. Lymph follicles were small but active. The lymph nodes were moderately enlarged but exhibited nothing remarkable microscopically.

There was no evidence of obstruction in the extrinsic bile ducts. The liver was slightly smaller and softer than average; the parenchyma was dark brown and the lobules were indistinct. Microscopically there was considerable distention of the sinusoids; otherwise nothing remarkable was seen. An anatomic basis for the jaundice was not demonstrable. The pancreas was much smaller than average and appeared atrophic both grossly and microscopically. Diffuse fibrosis was readily seen microscopically, as was a striking distortion of the islands of Langerhans. Many of the cells were pyknotic and widely separated. The total number of cells in each islet seemed reduced.

The kidneys were of average size and presented no significant findings grossly or microscopically other than moderate congestion. The adrenal glands showed moderate atrophy of the cortical tissue and pronounced vascular engorgement. The thyroid gland was diffusely hyperplastic, was considerably infiltrated by lymphocytes and contained a few small areas of fibrosis. The pituitary gland and brain presented no abnormality to either gross or microscopic examination.

CONCLUSIONS

Both the clinical diagnoses diabetes mellitus and toxic diffuse goiter are supported by the anatomic alterations. Death in this case doubtless was due to the agranulocytosis with its subsequent agranulocytic angina. The terminal jaundice appears to be explainable only on a basis of toxic hepatitis. It seems quite possible that if polymorphonuclear leukocytes had been available there would have been an anatomic evidence of a toxic hepatitis. In view of the ability of thiouracil to produce leukopenia and agranulocytosis, it is assumed that thiouracil was the basis for the agranulocytosis and toxic hepatitis in this case.

The severe diabetes mellitus is believed to have been a contributory factor in the death of this patient.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following article.

HOWARD A. CARTER, *Secretary*.

OCCUPATIONAL THERAPY IN A PRIVATE GENERAL HOSPITAL

JOHN S. COULTER, M.D.

CHICAGO

Occupational therapy is an objective treatment prescribed by a physician to hasten a patient's recovery from disease or injury or to contribute to his adjustment to hospitalization.¹ The activities used as treatment must be sufficiently interesting to the patient to motivate his active participation. The occupational therapist must be trained professionally to carry out the physician's prescription to select and adapt activities which meet the patient's physical and psychologic needs. The occupational therapist should be a graduate of a school approved by the Council on Medical Education and Hospitals and registered by the American Occupational Association.

Occupational therapy is divided roughly into the following groups:

1. *Preventive or Diversional Therapy*.—This type of occupational therapy comprises simple prescribed activities, including recreation, which serves to induce rest, to control general exercise, to prevent neuroses and to sustain morale.

2. *Functional Therapy*.—This type comprises prescribed activities planned to assist in the restoration of articular and muscular function, to improve the general condition, to build physical endurance and to aid in mental rehabilitation and in the treatment of mental disorders. Aitken² has shown the value of functional occupational and physical therapy in the rehabilitation of the industrial casualty.

3. *Prevocational Therapy*.—This type comprises work processes planned and prescribed to prepare a patient for his return to his former employment or for vocational education.

Most large general hospitals maintained by county, state or federal funds have an occupational therapy department. A statement concerning the coordination of the physical and occupational therapy departments by Watkins³ emphasizes that the combined departments should be directed by a physician specializing in physical medicine. The technical personnel in his department consist of a supervisor of physical therapy with six assistants, and a supervisor of occupational therapy assisted by two full time and one half time occupational therapists.

It is believed that every general hospital regardless of size should have an occupational therapy department, because it is as necessary as a physical therapy department and any other therapy. The occupational therapy department should be in the department of physical medicine and under the supervision of a physician specializing in physical medicine. Most private general

hospitals will soon require a department of physical medicine (physical and occupational therapy) in order to carry out the federal-state programs for crippled children, the federal-state programs of physical and vocational rehabilitation and to enable them to care properly for many casualties of civilian industry.

Some insurance companies have begun to establish physical and occupational therapy departments as curative workshops or rehabilitation centers, as units separated entirely from hospitals. The advantage of this plan is that the patient does not feel that he is returning to the hospital for treatment, but the one disadvantage of the plan is that the doctor who originally treated the patient does not see him often. Lieut. Col. Raymond Hussey, M. C., U. S. Army, formerly chairman of the Board of Occupational Diseases, Department of Labor, and chairman of the committee on Workmen's Compensation, Council on Industrial Health of the American Medical Association, states "It is unfortunate, I think, that physical and occupational therapy clinics are organized separately from hospitals, since we all realize that physical and vocational rehabilitation procedures should be given simultaneously with medical and surgical treatment."

Recently an insurance company writing workmen's compensation insurance established a rehabilitation center for cases requiring physical and occupational therapy. The president of the company stated that in some instances of extended convalescence his experience showed that there was a considerable amount of difficulty in the achievement of complete recovery and a working status. In order to determine a solution, the company established the Rehabilitation Center. After a year of operation this insurance company was convinced that efficient physical and occupational therapy, under medical guidance, supplies a satisfactory solution to this problem and that rehabilitation should be instituted as soon after injury as possible. This indicates that rehabilitation should be started in the hospital.

In the last three editions of the Handbook of Physical Therapy some activities of the occupational therapy department at St. Luke's Hospital in Chicago were described. St. Luke's is a general hospital containing 485 beds and supported by private endowments and contributions. In order to illustrate the financial arrangements of an occupational therapy department, St. Luke's Hospital can be cited as an example.

For twenty-five years no charge was made for occupational therapy, because it was classed as a necessary adjunct of hospital service. Two years ago the chief of the medical staff thought that, as occupational therapy was a method of treatment, a charge should be made. These charges are now \$1 per treatment for occupational therapy alone. When occupational therapy is combined with physical therapy, a minimum charge for the first hour or major fraction thereof is 50 cents and each additional hour or major fraction thereof is 25 cents plus the charges for physical therapy treatments. It was as difficult to introduce this added fee for occupational therapy as it would have been to launch a new department. Nevertheless, almost \$900 was received during the first year.

General hospitals should maintain capable occupational therapy departments that can practice preventive or diversional therapy. Without occupational therapy many patients are unable to make the necessary social and institutional adjustments so essential to their recovery. The majority of hospitals provide libraries and radios, and occupational therapy is as important.

1. Manual of Occupational Therapy, Chicago, American Medical Association, 1943.

2. Aitken, A. P.: The Rehabilitation Center, Rhode Island M. J. 26: 286 (Dec.) 1943; Rehabilitation of the Industrial Casualty, Virginia M. Month. 71: 177 (April) 1944.

3. Watkins, A.: Occupational Therapy and Rehabilitation 22: 115 (June) 1943.

The physical therapy and occupational therapy departments at St. Luke's Hospital are under the direction of a physician specializing in physical medicine. In the occupational therapy department are two registered occupational therapists, and usually there is one occupational therapy student who is receiving instruction in the practical phase of this work.

When occupational therapy is being carried out the posture assumed by the patient is most important, whether the patient is in bed or sitting in a chair. Wherever possible, the occupational therapists should see that the following instructions are observed:

I. Regulate Positions in Bed.—*Recumbent Position:* This position serves to prevent deformity and to improve general circulation.

A. Flatten the mattress: It is preferable to eliminate the pillow from under the head. A flattened chest and a slowing up of the circulation will result if a pillow is used.

B. Place a small pillow or roll under the knee joint. Subluxation of the knee frequently results if this procedure is neglected.

C. Train the patient to lie with his elbows and wrists extended to prevent flexion deformities. The arthritic patient frequently assumes a position in which he flexes the elbows and wrists and rests them on his chest for comfort and body warmth. The pressure of the arm on the chest retards full inspiration and slows up circulation.

D. Prevent deformity of outward or inward rotation of the hips by propping the legs in a correct position with pillows or sandbags.

E. Maintain a 90 degree angle of the ankles and prevent foot drop by using a heavy box or bricks at the foot of the bed to hold the feet at right angles and prevent pressure of the bedclothes.

F. Arrange the equipment so that the patient lying flat on his back may maintain a good functional position.

II. Sitting Position.

A. If possible use a flat canvas or board back rest. If a pillow is used it should be firm and extend from the hips to the shoulders. The chin should be in, the head back and the chest high. A firm pillow or roll under the head of the tibia to flex the hip and knee will prevent the patient from slipping down in bed and assuming a poor position.

B. The patient who is allowed to sit up for his occupational therapy should be in a good functional position.

III. Position in a Chair.—Whether a wheel chair or a regular chair is employed, it should have a straight back. While the patient is sitting up he should be erect with his chin in and chest high. If a pillow is used it should be placed below the shoulders so that the head is not pushed forward and the chest not flattened. The occupational therapist should see that the patient is seated correctly while at work.¹

MENTAL DISEASES

Although St. Luke's Hospital is a general hospital, it has one floor for mental diseases. Here the occupational therapy department has one room (locked when not in use) devoted to these cases. Occupational therapy treatment is given in accordance with the principles of McGraw and Conrad.⁴

In the handling of neuroses the department utilizes occupational therapy as an aid in overcoming the tendency to avoid responsibility, in increasing the feeling of potency, in directing the desire for approval that is characteristic of the hysterical into more useful channels and in the allaying of the restlessness of anxiety.

If the occupational therapist is tactful, manic patients with agitated depressions may be persuaded to work

quietly and to confess later that they have begun to feel more normal when thus occupied. The warning that cannot be too often stressed is that suicidal attempts come, not at the period of greatest inertia, but just at the time when the patient is starting into or coming out of a depression, so that many patients who are just beginning to take an interest in occupational therapy may also be interested in using dangerous tools with great cunning and consequent menace to themselves. The same caution about tools is necessary when dealing with paranoid patients, but those institutions in which paranoids create a minimum of disturbance and are most contented are the institutions that have promptly provided a suitable occupation for each individual. If furnished with an outlet, the drive of these patients is much less violent; but the physician should be aware of an increase in tension among those who have long been permitted to use dangerous tools.

A helpful concept is to grasp the patient's interest at the emotional age level at which we find him living.

The problem in the acute phase of schizophrenia is not so much that of catching the attention of the patient as in maintaining his interest. We cannot be positive as to whether novelty or old habits should be relied on at this point. One patient with acute schizophrenia will be confused by unaccustomed procedures; another will block when old habits call up old conflicts. Not infrequently a woman having a paranoid precox will want to do carpentry or other work that she considers to be a man's occupation.

Generally a patient's expressed wishes to attempt any specific work is gratifying and well worth trying. Some occupational therapists may permit the patient to work out unconscious conflicts with symbolic objects, similar to the method which child psychologists use when they employ toys. This application is truly an analysis and requires all the safeguards of that technic. Dr. Conrad believes that in other than an exceptional case the major aim should be the progressive return of the individual to satisfaction and self confidence in participation in normal living. It is the responsibility of the physician to see that the procedure is adapted to the patient's individual problem.

A most delicate and often treacherous part of the treatment is in prescribing the work. It is rarely advisable for the physician to do this alone, and there are dangers in leaving it all to the therapist. Experience teaches us that correspondence to and fro is time consuming and frequently unsatisfactory; nevertheless there should be some sort of joint action, and records should be kept.

In group treatment it is inevitable that various persons often compete for the credit of the cure and for the loyalty of the patient. We hear from nurses, from recreational aids and from occupational therapists "If I had more of a chance, I'm sure I could have accomplished so much more." Sometimes this is pure rationalization. Occasionally it is valid and might well be heeded at the risk of upsetting the routine a bit. The danger of presenting projects too simple for the highly intelligent, cultured and gifted patient should be borne in mind. This requires fine discrimination on the part of the technician and also an understanding of the background and personality of the patient. This information should be available in adequate record form for the therapist.

We are living in an age of specialization. Occupational therapy is a specialty and as such must bear the

4. McGraw, R. B., and Conrad A., quoted by Backmeyer, A. C., and Hartman, G.: *The Hospital in Modern Society*, New York, Commonwealth Fund, 1943.

criticism as well as the praise due it. Some say that society, industry and medicine have all been overspecialized, and it is therefore somewhat of a paradox that the cry of "back to the patient" has been raised in the past decade. In opposition to the overspecialization is the precept "Treat the whole patient, not just his disease." Occupational therapy is much involved at this point.

Occupational therapy can help people find a better use of their leisure time. Illness and convalescence, even mental illness, such as neuroses and psychoses, provide a convenient opportunity to introduce this principle. Interest will develop in the creative arts and crafts and in craftsmanship, and perhaps also in cooperation with others.

The "joint action" mentioned in this article is accomplished at St. Luke's Hospital by using requisitions which state diagnosis and occupational therapeutic precautions for each patient. These requisitions are made out and signed by the physician in charge of the case. They are supplemented by frequent visits of the psychiatrist to the occupational therapy department and by notes on the clinical record made by the occupational therapist.

The occupational therapist uses a great deal of recreational therapy through the monthly parties and dances for the patients, through games and through social activities.

Functional occupational therapy is usually given in a workshop, which, in a general hospital, should have large enough floor space to assist in the restoration of articular and muscular function in order to build up physical endurance and to aid in the whole physical and mental rehabilitation of physically handicapped patients. In these cases the coordination of the physical and occupational therapy departments is most important. St. Luke's Hospital is planning to enlarge the floor space of the occupational therapy department.

Rehabilitation is the planned attempt, through the use of all recognized measures under skilled direction, to restore those persons who, because of disabilities, do not assume to the greatest possible extent and at the earliest possible time that place in the productive stream of society of which they are potentially capable.⁵ Rehabilitation of the injured must therefore start at the patient's bedside and must be continued during and after the patient's stay in the hospital.

Rehabilitation of the injured requires the cooperation of many services, such as surgery and psychiatry.

Often patients have a psychologic protracted convalescence, and it is therefore necessary to use psychotherapy. The Physical Medicine Department of St. Luke's Hospital employs Solomon's⁶ method in these cases. It has four major divisions:

1. Psychologic understanding of the patient's character in order to avoid emotional trauma to his personality during all his professional and industrial contacts.

2. Psychiatric evaluation of the patient's emotional problems, both related and collateral to his accident, in order to clarify the dynamic meaning of his attitudes and make him understand his own behavior.

3. Careful supervision of all the psychologic aspects of his return to employment so as to avoid maladjustment and, if possible, improve his previous work adjustment.

4. Institute at the first evidence of psychologic protracted convalescence a recreational and exercise program.

Griffiths⁷ calls attention to several principles which should be observed in giving functional occupation therapy. He writes:

The injured man must be divided into two categories. The cripple must have work to do from the outset so that he shall see that he still retains the ability to work. The recoverable must not have any treatment that removes⁸ resembles his daily work, lest his pain or temporary clumsiness should instill in his mind fear for his ultimate recovery.

Prolonged exercise is often better obtained by exercises designed to interest the patient and to divert his attention from the particular group of muscles which we want to exercise. Griffiths suggests:

A choice of exercise is easily made which will achieve the desired movement in each patient without his being conscious that this exercise is deliberately designed to produce that movement. For example, if a group of patients contain one man in whom it is desired to strengthen the vastus internus muscle of the leg by repeatedly bracing the knee, a second in whom it is desired to hyperextend the spine, a third to flex the hip joint, a fourth to raise the arm at the shoulder, these men may be given the simple exercise of bouncing a rather soft football on the floor of a gymnasium hard enough to reach the ceiling. It will be found that, in spite of themselves, the desired movements will be attained time after time during the short period this exercise may be continued.

Functional occupational therapy in St. Luke's Hospital is used in orthopedic and surgical cases in such conditions as fractures, dislocations, strains, sprains, contractures due to burns, lacerations of tendons and peripheral nerve injuries and chronic arthritis and in other injuries. In these cases the prescribing of occupational therapy is based on the fact that the best type of remedial exercise is that which requires a series of specific voluntary movements which form an integral part of a more complex series of coordinated movements for the purpose of securing the end products and thus furnishes direct incentive for sustained effort.

In cases caused by injury it is believed that the occupational therapist would do well in following Kennedy's⁸ suggestions that active exercise should be prescribed as soon as the fracture has been reduced, when the method of fixation has been decided on and when the fixation has been effected. A fracture patient enters the hospital as a healthy man with a fracture and not as a man physically or mentally sick. The less he is placed in the category with the sick patient, and the more he is treated as one who was well before the accident and who expects to remain well, the shorter will be his convalescence period. Because a leg is injured is no excuse for allowing the muscles of the neck, back and the three other extremities to deteriorate and to prolong greatly the convalescence.

The fracture patient needs work therapy—not a vacation but a hardening process. Ways and means should be devised to keep his mind and body occupied from the very beginning.

Occupational therapy needs to be introduced much more widely in general hospitals because, according to Kennedy, occupational therapy is many times more valuable than the usual types of physical therapy for these patients. As an occupant of a general hospital, the fracture patient is too often conditioned to become

8. Kennedy, R. H.: Active Exercise in Fracture Treatment. *Arch. Phys. Therapy* 22: 720 (Dec.) 1941.

ing an invalid. Frequently he requires prolonged care to recover from his hospitalization rather than from his injury.

A fracture patient should be taught how to use all joints and muscles in the region of immobilization, commencing on the first day. He should be given general exercises immediately in order to preserve his musculature. While he is in bed he should be given a job that will occupy both his body and his mind and make him feel that he is still part of the moving world. As soon as the fracture patient leaves his bed he should be taught by some form of occupational therapy and, if possible, something similar to the type of work he performed before his accident.

In the curative workshop power reduction factors, such as psychologic inhibitions, pain, fear and fatigue, are eliminated as much as possible.

It is believed that the psychologic inhibitions of the workshop require that the environmental conditions there be superior to those of the man's normal environment. If one can surround the patient in the workshop with a feeling of well being beyond that to which he is accustomed, one will have accomplished a great deal. This sense of well being can be accomplished by interior decoration, orderliness and absolute cleanliness. To motivate a convalescent patient to leave the ease and lazy life of his personal environment requires that he make considerable mental effort, and this effort can be stimulated through the patient's desire to be in a workshop.

Pain can be lessened by cooperation between the hospital staff and the physical therapy department. The physical advantages of the curative workshop situated close to the physical therapy department are obvious. By heat, diathermy, whirlpool bath, massage and muscle stimulation, pain is diminished and exercise is facilitated.

The patient's fear should be eliminated by cooperation between the occupational therapist and the patient's employer. The physician in charge of a department of physical medicine and the occupational therapist should not give testimony about the patient's condition for the insurance company or for the employers before a court or a workman's compensation board. If this is done, the news is spread that the occupational therapy department is trying to get the patient back to work, not for his benefit, but for the insurance company. This causes fear in all the patients and a consequent loss of confidence in the workshop.

The patient's fatigue can be guarded against by cautioning him that no form of work or play should be continued for more than a relatively short time. Fatigue can be measured in the arm by a hand grasp strength test and in the leg by a pull test for the quadriceps muscle. Fatigue may be mental as well as physical, and for this reason a curative workshop should have both recreational therapy and exercise classes.

Recreational therapy, through competitive games, can often supply the desired exercises that the patient requires. The devices used may be a checkerboard on the floor or wall, darts, pingpong, horseshoes and pool tables.

Recreation gives mental relaxation after the workshop. Games are played with the technician and are manipulated in such a way that the patient is encouraged to strive against and to excel the technician. During rehabilitation of an injured man, one may spend a long period of time training him vocationally, but if he is

unable to achieve his proper position under social conditions he will never become really rehabilitated. A man must be helped to adjust himself to a group and to be at ease in conversation with his companions so that he can join in the games of the group and become a part of it. Citing one example: A man came to the department with an artificial hand. Although we were successful in encouraging him to use both his hand and his arm to saw wood, to hammer nails and to do a pretty good job in the wood working shop, he did not feel at ease socially and kept his artificial hand in his pocket when not in actual use. It was not until he found he excelled at the pool table that he realized that although he had an artificial hand he was on a par with others. Thus, social accomplishment played an important role in his future life.

Classes in remedial exercises not only give therapeutic exercises but may eliminate mental fatigue. Dr. Storms in his Workmen's Compensation Clinic in Toronto, Canada, makes excellent use of these classes. He conducts classes for leg exercises from 9 to 9:30 a. m. and 1:30 to 2 p. m., foot classes from 9:30 to 10 a. m. and 2 to 2:30 p. m., hand classes from 10:45 to 11 a. m. and 3 to 3:15 p. m., and arm exercise classes from 11:30 to 12 m. and 4 to 4:30 p. m. In the leg classes the patients (1) walk over a floorlike apparatus built to simulate uneven ground, (2) walk over a MacKenzie inversion tread, (3) walk over steps of various heights, (4) along a bench 18 inches high and 10 feet long to preserve balance and induce good posture, (5) climb up and down a platform with ladders on both sides 5 feet high, five ladder rungs to climb to the top where there is a platform 3 feet long protected on the sides by 30 inch high hand rails, with another ladder on the end, so that it necessitates climbing up five rungs and down five rungs (fig. 1), and (6) work on a treadmill with hand rails. These classes are organized into groups, and every man with a leg disability attends the leg exercise classes as soon as he is able to do so. The hand and arm groups complete hand and arm exercises with the patients sitting in chairs.

In the treatment of the injured workman, Griffiths' observations on the conditioned reflex of industry should always be observed. He says in part:

The conditioned reflex adds the power producing factor of repetition, and this in the deliberately acquired reflex was originally the result of conscious effort. Impulsive action, although not a truly acquired conditioned reflex, is produced by the cortical memory of deliberate action freed by practice from psychological inhibitions associated with conscious deliberation. Deliberate action becomes an effort of will power or thought; but for deliberate muscle action to be developed into a state of skilled muscle action a period of training is necessary, requiring concentrated mental effort and practice, and this can only lead to the desired skilled action as experience is obtained. Finally, something more is needed before the skill becomes expert. This extra something is not only experience but represents a definite advance in pure psychical effort.

The inhibition of the conditioned reflex may be either external or internal. The external inhibition is produced by some excitatory processes other than the conditioned stimuli in the central nervous system, and of these pain, the anticipation of pain or other fear are of greatest importance.

The conditioned reflex of industry is a very complex affair. Take, for example, the skilled carpenter using a saw. The action is one of pushing and pulling the saw, but long practice has produced a conditioned reflex in which each stroke of the saw corresponds almost exactly with the previous or succeeding strokes. The reflex developed is a nice example of negative

successive induction, but it is not the simple affair of alternate contraction and relaxation of the biceps and triceps or of the serratus magnus and latissimus dorsi muscles. The beautifully balanced muscle action involved depends on many different conditioned stimuli.

Fig. 1.—Apparatus for leg exercises at Workmen's Compensation Clinic, Toronto.

To mention only a few of these: There are the touch stimuli from both hands. In the saw hand a definite tactile discrimination is associated with the man's own saw (as every tradesman uses his own tools). Thus the same part of the skin of his hand is stimulated every time he grips this particular saw. There is the stimulus of bone vibration set up by the wavelength of the saw being used, so that the farther the saw is thrust the shorter the vibration wave, ultimately suggesting the point at which the reflex action of the thrust shall be reversed. There is in addition the sound reflex, the rasp of the saw, and here again the note alters with the progress of the saw through the wood. When the conditioned reflex is first established a knot in the wood will cause a temporary interruption in the reflex path and tend to throw the muscles out of proper coordination so that there must be a period of conscious action before reflex action is reestablished. But as time goes on the extra resistance of a knot in the wood itself produces a superimposed conditioning stimulus and sets forth a bigger muscular effort without interfering with coordination.

In considering all these industrial conditioned reflexes the law of summation of conditioned reflexes must be borne in mind. This states that when different conditioned stimuli will each call forth a similar reflex, the stimuli acting together will produce a greater effect than they do when acting alone. A conditioned reflex may be reduced but not lost by interference

with one of the conditioned stimuli, provided the other conditioned stimuli are sufficiently strong to overcome the inhibiting effect of the lost stimuli.

With the injured workman, bed treatment is only a minor problem. Over 99 per cent of the injured can and should receive ambulatory treatment, and this must be designed to ensure that they use their conditioned reflexes and so secure the maximum amount of exercise with the minimum amount of fatigue. Man's ordinary walking gait is a combination of postural reflexes with the stepping reflex and various conditioned reflexes, not the least of which is produced by the sensation of the impact of the ground transmitted through the sole of a shoe or boot. Treatment therefore must be aimed at restoring normal walking conditions at the earliest possible moment.

Finally we come to the question of vocational exercise associated with the patient's work. This aspect of treatment must be attempted only when its practice will not produce any of those factors which inhibit the conditioned reflexes which are the foundation of his skill.

As an example take the carpenter who has an injured wrist and is asked to use a screwdriver. The normal action of driving a screw is for him a conditioned reflex, but pain inhibits this reflex action and it does so in this way: In the first turn made, perhaps the normal conditioned reflex was obtained, but with it pain; the movement now becomes conscious movement and the anticipation of the pain produces a static

Fig. 2.—Apparatus for arm and shoulder muscles. A man patient exercising his grip and shoulder muscles at Rehabilitation Center, B.

contraction of muscle to resist the anticipated movement. This inhibits the conditioned reflex with resultant incoordination of muscle action and loss of power. But the effect does not end there. With pain and work linked in the man's mind, fear is born—the fear of incapacity for work—and this fear further inhibits the conditioned reflex. It has been a mistake, therefore, to attempt to restore the conditioned reflex of the

man until the arm has become relatively free from those factors of pain and stiffness which would inevitably inhibit the desired action.

What has been said of vocational therapy applies equally to so-called "light work." The man has been given work of a

Fig. 3—Gravel box and adjustable fence apparatus for reconditioning an industrial conditioned reflex at Rehabilitation Clinic, Boston.

lighter character in his own trade before he is sufficiently free from pain and while still liable to early fatigue. As a result, he develops inhibition of his previously work-conditioned reflexes, leading to increased clumsiness and to despondency. If he has not been employed at the lighter forms of his old job, all too often he has been given work which involves industrial degrading—a bricklayer becomes a tea-boy—and one of his worst fears is realized. His mind now becomes so concentrated on the injured part that subconscious movement becomes almost impossible and the most rapid road to recovery—restoration through exercise—is barred to him.

We are enlarging the floor space of St. Luke's Hospital Curative Workshop to give our patients the necessary work to take advantage of the industrial conditioned reflexes. Dr. Storms in the Workmen's Compensation Clinic at Toronto, Canada, gives his patients occupational therapy that eventually works into industrial conditioned reflexes.

Following are some examples of Dr. Storms's occupational therapy workshop: A bricklayer with a disabled hand was given a thousand bricks and told to arrange a part of them in a design on the floor first. Later the bricklayer was handling all the bricks without mortar, to build walls. He knew how many bricks he needed to handle at his job each day, and from the number he was able to handle each succeeding day in the workshop he saw how he was improving and how close was the time of his return to work. A sign painter was ready for work, except that his grip and shoulder muscle were not strong enough for him to pull on the ropes that raised and lowered his swinging

scaffold; Dr. Storms rigged overhead a compound pulley and had the patient pull on a rope and lift weighted bags of sand attached to the other end of the rope, just as was done at his occupation. When he was able to lift a certain weight, the painter was confident that he was ready to return to work.

A brake is also arranged for switchmen in this workshop, and there is a platform built waist high for freight workers. Ordinarily boxes are filled with weighted loads. The disabled patient loads the boxes onto a wheelbarrow and wheels them to another place, where he then unloads. A large tree trunk to saw with cross cut saws is provided for lumberjacks. Wood is split by blacksmiths or other workmen who employ mallets or hammers. A gravel box is provided with a fence that can be varied in height. Laborers who use shovels at their work can shovel gravel over this fence (fig. 3). Dr. Storms has rigged hand and foot levers which are weight regulated by cans or bags of sand attached to the beams for steam shovel operators (fig. 4). Painters are given work with paints and brushes in this workshop.

This principle of occupational therapy sometimes results in rather humorous situations. A tombstone engraver was injured in the arm. In the workshop he was provided with a cutting stone and other tools of his trade. During the course of his treatment he engraved "In loving memory of" and the names of the physical and occupational therapy technicians on a tombstone.

Occupational therapists are required to visit the industries, railroads or other places where the patients had been employed prior to their admittance to the hospital in order to observe men at work in these industries and therefore to be better equipped to devise occupational therapeutic apparatus and to prescribe methods to fit the disability of the patient with due consideration of his future employment. Therapists should know how hard the men must work in a given trade and what the trade names are for each occupation. If a patient states that he is a "holder-up," the occupational therapist should know that he "holds

Fig. 4—Apparatus for reconditioning industrial conditioned reflexes at Workmen's Compensation Clinic, Toronto. A steam shovel operator pulling hand lever where resistant force is regulated by positions of weight attached to beam.

a dolly for the rivet" and should also know what a "dolly" is and weighs, what muscles are affected in this operation, what the joint movements are and what the patient requires in the methods of occupational therapy in order to get him back to his work.

Occupational therapy is one of the best forms of treatment for injuries. It diverts the patient's mind from his injury and improves his morale. Mock¹⁰ stated in a previous edition of the Handbook of Physical Therapy:

One of the commonest causes for traumatic neuroses is failure of continuous active treatment until the surgeon is assured that his patient is well on the way to an economic end result; that is, able to carry on once more. The diagnosis of a broken back, a skull fracture or a fractured pelvis often strikes fear and dread into the heart of the patient; yet the treatment of these conditions in a large majority of cases is comparatively simple and the end results are extremely good. Many times treatment consists in simply putting the patient to bed and keeping him as quiet as possible from six weeks to three months or, in some cases, in addition to rest, of traction applied to the lower extremities. The surgeon makes his daily round satisfied with the treatment of the physical condition and the progress being made and never recognizes or even dreams of the fear and anxiety that are gnawing at the patient's mind. When the day comes for the patient to leave his bed and begin to move about, the surgeon is disgusted with the lack of cooperation on the part of the patient, the unwillingness to try to help himself and the absurdity of his complaints.

All such patients, in addition to the actual surgical treatment, need properly directed physical therapy and occupational therapy, which are the logical adjuncts to the usual surgical procedures. . . . Occupational therapy keeps a patient's mind and hands employed for a large part of the day, filling in the gaps between the surgeon's visits and the physical therapy and leaving little time for the fears and germs of traumatic neuroses to develop.

CARDIAC CONDITIONS

One of the big workmen's compensation insurance companies recently stated that the patient with heart disease but with good compensation may do well in special placements which do not require physical effort sufficient to aggravate the crippled part. In the average stable industry there are about 8 per cent of the entire personnel who are cardiac patients. This group of trained artisans need not and should not be discarded. With proper medical supervision, with shifting of placement and general oversight, they can continue in active service for many years without shortening or jeopardizing their lives. This group does not include the many persons who die suddenly of a heart attack and who had previously shown no symptoms referable to the heart. Dr. W. D. Stroud, a member of the Council on Industrial Health of the American Medical Association, published a detailed discussion of this subject.¹¹

FUNCTIONAL CLASSIFICATION OF PATIENTS WITH HEART DISEASE

CLASS I.—Patients with Heart Disease and No Limitation to Physical Activity.—Ordinary physical activity does not cause discomfort. Patients in this class do not have symptoms of cardiac insufficiency, nor do they experience anginal pain.

CLASS II.—Patients with Heart Disease and Slight Limitation to Physical Activity.—Patients in this class are comfortable at rest. If ordinary physical activity is undertaken, discomfort results in the form of undue fatigue, palpitation, dyspnea or anginal pain. Competition in athletics and other strenuous activity, even hurrying, are to be avoided. Activity should be graded according to cardiac tolerance. A vocational plan

should be made according to the permanent mechanical involvement of the heart.

CLASS III.—Patients with Heart Disease and Pronounced Limitation of Physical Activity.—Patients in this class are comfortable at rest. Discomfort in the form of undue fatigue, palpitation, dyspnea or anginal pain is caused by more than ordinary activity. Occupational therapy is first used to induce rest from the cardiovascular standpoint, allowing the circulation to slow down and the reserve power to overcome infections. By this means ultimate damage is minimized. Light activities and a program of graded exercise may later be indicated.

CLASS IV.—Patients with Heart Disease and Inability to Carry on Any Physical Activity Without Discomfort.—Symptoms of cardiac insufficiency or of the anginal syndrome are present in patients in this class, even at rest. If any physical activity is undertaken, discomfort is increased. In this class, as in class III, occupational therapy is used to induce rest as well as to decrease anxiety and fear. The program is limited to mental activity and may prove of distinct value as a palliative measure.¹²

In a large general hospital, such as St. Luke's Hospital, the occupational therapy department is frequently ordered to give preventive or diversional occupational therapy to persons with heart disease. It is believed that these patients should be given functional occupational therapy in the curative workshop to improve their general condition, to aid in their mental rehabilitation and to aid their attending physician to prescribe the amount of exercise that his cardiac patient can take. Too often such a patient is sent home from the hospital with such inadequate instructions concerning exercises as "Do not overdo." Although exercise cannot be definitely prescribed, it should not be left entirely to the discretion of the patient. Mackenzie¹³ maintains that the object of exercises—the strengthening of the heart muscle—is too often forgotten. He states that, by summarily laying down that so many yards should be walked one day and so many another day, the physician shows that he has failed to take into account the peculiar nature of the heart functions. The power of response of the heart to effort varies greatly in the same individual from time to time—one day a patient with an impaired heart can undertake a great deal of effort with comparative comfort, whereas on other days the same amount of effort causes him distress. This is because the heart may be disturbed by a variety of conditions such as gastric or intestinal disturbances, lack of sleep and the state of the weather. The patient's sensations are therefore a valuable guide and may indicate the amount of effort which can be undertaken by him with safety in all circumstances.

Stroud and Comstock¹⁴ state that patients with organic heart disease who are unable to carry on any physical activity need occupational therapy which gives practically absolute rest from a cardiovascular standpoint. Here, remuneration for articles sold, future vocation and so on should be minor considerations. If practical they should certainly be taken into account, but not at the expense of the main object of such therapy; that is, mental and physical rest in order to

relieve the circulation of much of the load which the heart must carry. It is the relief from this burden which allows the heart muscle, previously unable to carry on its work of keeping up an efficient circulation, to regain much of its reserve, so that if it is not again asked to carry too heavy a load it may do its work efficiently for many years. Proper occupational therapy, by lightening the burden placed on the circulation by mental and physical activity, may, in children with active infections damaging their heart muscle and heart valves, allow circulation to slow down and thus help these children to call on their reserve to overcome the active infection and minimize the ultimate damage to their hearts. These are the two large groups which come under the class of patients with organic heart disease who are unable to carry on any physical activity, those with active infections damaging the heart and those with already damaged hearts which have been required to carry too heavy a circulatory burden through physical and mental effort and whose hearts have temporarily failed. These authors further state that, when such patients progress so that they are able to carry on diminished physical activity or their habitual physical activity, vocational training with the ultimate object of a definite vocation, and finally placement through a bureau for the handicapped, are as important as is the occupational therapy itself.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN E. SMITH, M.D., *Secretary.*

PENICILLIN.—A solid extract of organic nature obtained from certain molds which possesses the property of being able to inhibit the growth of and even occasionally actually destroy certain bacteria. It may be prepared as several salts, including sodium, calcium and ammonium salts.

Actions and Uses.—Penicillin belongs to a class of agents frequently referred to as antibiotics and antimicrobial agents of biologic origin. At present, penicillin is prepared by culture methods and not synthetically. In finished form the powder usually has a brown or yellow appearance and is marketed in air-tight ampuls. The material is unstable in air, hygroscopic and subject to rapid reduction in potency on exposure to heat and acids. Thus the ampuls are stored in the refrigerator and the contents put into solution only as needed. Penicillin is very soluble in water and in saline and dextrose solutions. At present the potency of penicillin preparations is determined by biologic assays, a method which essentially is concerned with the inhibition of the growth of a certain strain of *Staphylococcus aureus* in special medium; this is compared with a standard, and the result is expressed in Oxford units. All specimens also are examined for moisture content, freedom from pyrogens, sterility and toxicity.

Penicillin is indicated in staphylococcal infections with and without bacteremia, clostridial infections, hemolytic and anaerobic streptococcal infections, pneumococcal, gonococcal and meningococcal infections, and the complications caused by such infections. It may prove valuable in syphilis, actinomycosis and bacterial endocarditis, but such use is yet in the experimental stage. Subsequent uses depend on current and forthcoming research.

Dosage.—Penicillin may be administered intravenously, intramuscularly, intracisternally and topically. Subcutaneous injections may be painful. Treatment may consist of repeated intramuscular or constant intravenous injections. The contents

of an ampul, or ampuls, are dissolved in sterile, pyrogen-free distilled water or isotonic solution of sodium chloride. For intravenous injection, concentrations of 1,000 to 5,000 units per cubic centimeter are prepared for direct injection, or 25 to 50 units per cubic centimeter for constant intravenous therapy; for intramuscular injection, 5,000 units per cubic centimeter of isotonic saline solution; for topical application (not the sodium salt in powder form, as it may be irritating when applied locally), 250 units, or more if infection is severe, per cubic centimeter of isotonic saline solution; for subarachnoid space, 10,000 units in isotonic saline solution in a concentration of 1,000 units per cubic centimeter injected once or twice daily; for empyema, 30,000 to 40,000 units injected after the pus has been aspirated. Penicillin solutions should not be used for irrigation.

The dosage of penicillin will vary according to patient and severity of infection, but the objective is to bring the infection under control as quickly as possible. Inadequate dosage may create penicillin resistance in the invading organisms. Penicillin is excreted rapidly, and injections should be repeated every three or four hours unless continuous infusion is employed. In serious infections with or without bacteremia, an initial dose of 15,000 to 20,000 units followed by constant infusion to supply 2,000 to 5,000 units every hour or, in the absence of constant injection, 10,000 to 20,000 units injected intramuscularly every three or four hours, may be employed. After the temperature has returned to normal, the penicillin may be stopped, but the course of the disease must be watched carefully.

In chronically infected injuries, the dosage may be 5,000 to 10,000 units, or more if indicated, every two to four hours with local treatment as indicated. In no instance should proper surgical intervention be omitted. For sulfonamide-resistant gonorrhea, 10,000 units every three hours intramuscularly or intravenously for ten doses may be administered. Treatment depends on findings of culture of exudate.

WINTHROP CHEMICAL CO., INC., NEW YORK

Ampuls Penicillin Sodium: Each ampul contains 100,000 Oxford units.

PERCOMORPH LIVER OIL (See New and Nonofficial Remedies, 1944, p. 636).

The following dosage form has been accepted:

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Codanol Brand Percomorph Liver Oil 50% with Vio-sterol: 10 cc. and 50 cc. A source of vitamin A and D in which not less than 50 per cent of the vitamin content is derived from the liver oils of percomorph fishes with viosterol added. Each gram contains not less than 60,000 U. S. P. units of vitamin A and 8,500 U. S. P. units of vitamin D.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 608).

The following dosage forms have been accepted:

CARROLL DUNHAM SMITH PHARMACAL COMPANY, ORANGE, N. J.

Tablets Thiamine Hydrochloride: 1 mg., 5 mg. and 10 mg.

Solution Thiamine Hydrochloride, 10 mg. per cc.: 1 cc. ampul and 30 cc. vials. Each cubic centimeter contains thiamine hydrochloride 10 mg. in isotonic solution of sodium chloride, preserved with 0.5 per cent chlorobutanol.

TETANUS TOXOID, ALUM PRECIPITATED (See New and Nonofficial Remedies, 1944, p. 565).

The following additional dosage form has been accepted:

GILLILAND LABORATORIES, INC., MARIETTA, PA.

Tetanus Toxoid, Alum Precipitated (Refined): 50 cc. vials (25 immunizations) and 50 cc. vials (50 immunizations). Preserved with merthiolate 0.01 per cent.

SULFAMERAZINE (See THE JOURNAL, May 6, 1944, p. 31).

The following dosage form has been accepted:

E. R. SQUIBB & SONS, NEW YORK

Tablets Sulfamerazine: 0.5 Gm. and 0.25 Gm.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1944, p. 191).

The following dosage form has been accepted:

PREMO PHARMACEUTICAL CO., INC., NEW YORK

Tablets Sulfathiazole: 0.5 Gm.

METAMUCIL (See THE JOURNAL, April 15, 1944, p. 1133).

The following additional dosage forms have been accepted:

G. D. SEARLE & CO., CHICAGO

Metamucil: 4 ounce and 16 ounce containers.

SATURDAY, OCTOBER 7, 1944

HUMAN TOXOPLASMOSIS

The protozoan parasite *Toxoplasma* was discovered in the gundi, a North African rodent, by Nicolle and Manceaux in 1909. Protozoologists have found that *Toxoplasma* is pathogenic for a wide variety of mammals and possibly birds and has an extensive geographic distribution. Although the existence of a large potential reservoir of natural hosts, including dogs, rabbits, squirrels and voles, was known, the first verified human case of toxoplasmosis was reported by Wolf, Cowen and Paige¹ in 1939, just thirty years after the discovery of toxoplasma.

Once the pathogenicity of the parasite for man had been proved, reports of cases of human toxoplasmosis rapidly began to appear in the literature. Wolf and his associates² alone reported 9 more cases in the surprisingly short period of three years. Their pioneer studies established the basic features of infantile toxoplasmosis. They were dealing with a disease of young infants, in several instances proved to be acquired in utero and characterized by convulsions, changes in the cerebrospinal fluid, hydrocephalus, multiple calcifications in the brain and involvement of the retina by focal destructive lesions. In patients who survived the acute stage they found persisting or increasing hydrocephalus, nystagmus and permanent impairment of vision and usually some degree of mental retardation. They were much impressed with the destructive and granulomatous lesions in the central nervous system and retina but occasionally found lesions or parasites in extraneural tissues.

Meanwhile in 1940 and 1941 Pinkerton and his associates³ had reported 3 cases of fatal toxoplasmosis in adults with a different clinical picture resembling

typhus and Rocky Mountain spotted fever. But little involvement of the brain appeared in these cases. The main pathologic changes were diffuse interstitial pneumonia and necrotic and inflammatory lesions in many organs. Wolf and his associates encountered similar lesions only once, in a 3 day old infant, and speculated on the possibility of aspiration of toxoplasma infected amniotic fluid to account for the severe pulmonary lesions.

While there is on the surface little similarity between the acute typhus-like disease of adults and the encephalomyelitis of infants, the extraneural lesions occasionally found in infants indicate a pathogenic mechanism common to the two. Sabin⁴ had studied the pathogenesis of experimental toxoplasmosis and had shown that following multiplication at the site of entry the parasites are disseminated through the blood stream to every tissue, invading the vessel walls and ultimately the tissues themselves. The involvement of different tissues depends mainly on their susceptibility, regardless of the port of entry of the infection. In human fetuses and infants the central nervous system is especially susceptible. In a recent study based on 3 new cases of infantile toxoplasmosis, Zuelzer⁵ points out, however, that extensive changes in the visceral organs of infants may be more common than was formerly assumed. He found widespread lesions, including a severe myocarditis and interstitial pneumonia, besides encephalomyelitis, in an infant which died in the acute stage of the disease, and he was able to demonstrate minute residual lesions in the cardiac and skeletal muscles of a second patient with advanced cerebral and retinal damage. Zuelzer explains the pneumonia by the fact that all parasites must pass through the lungs during the stage of invasion. He states that the extent of the lesions found in the visceral organs depends largely on the stage of the disease. In most of the infantile cases the dissemination of the parasites occurs in utero some time before birth and thus the acute stage of invasion remains hidden. The lesions caused by toxoplasma tend to heal and may largely have disappeared by the time of birth except for the changes in the brain and retina, where the inability of nerve cells to regenerate allows conspicuous permanent lesions to develop. When the infection occurs shortly before delivery or after birth and the stage of invasion can be observed, the clinical manifestations may be expected to be more variegated and the disease more closely resembles adult toxoplasmosis. Further observations are needed before the complete picture of the disease can be drawn.

Early observations indicated that the mothers of infants with congenital toxoplasmosis fail to show evidence of the disease themselves. This was explained

2. Paige, Beryl H.; Cowen, David, and Wolf, Abner: *Toxoplasmic Encephalomyelitis*, *Am. J. Dis. Child.* 63: 474 (March) 1942. Cowen, David; Wolf, Abner, and Paige, Beryl H.: *Toxoplasmic Encephalomyelitis*, *Arch. Neurol. & Psychiat.* 48: 689 (Nov.) 1942.

3. Pinkerton, Henry, and Weinman, David: *Toxoplasma Infection in Man*, *Arch. Path.* 20: 374 (July) 1940. Pinkerton, Henry, and Henderson, R. G.: *Adult Toxoplasmosis*, *J. A. M. A.* 116: 807 (March 1) 1941.

4. Sabin, A. B.: *Toxoplasmosis*, in De Sanctis, A. G.: *Advances in Pediatrics*, New York, Interscience Publishers, Inc., 1942.

5. Zuelzer, W. W.: *Infantile Toxoplasmosis*, *Arch. Path.* 35: 1 (July) 1944.

after Sabin⁴ had perfected a serologic method permitting the demonstration of specific serum antibodies against toxoplasma not only in the patients but several times in their mothers and sometimes in other members of the family. Now it is clear that older persons may have subclinical toxoplasma infections. These findings at once widened the scope of future investigations. In the last five years 27 cases of human toxoplasmosis were reported in the continental United States. The presence of specific antibodies in apparently healthy persons means that the true incidence of human toxoplasmosis may be far greater than the number of clinically or pathologically recognizable cases indicates. This problem must await the development of a simplified method for the serologic diagnosis of the infection. The present method of Sabin seems reliable but not suited to general use.

Toxoplasmosis is rapidly becoming a disease of general interest. Search among the inmates of institutions for the mentally deficient has already yielded a number of previously unrecognized cases. The disease constitutes a known cause of mental retardation and of chorioretinitis. It concerns the neurologist, the ophthalmologist, the pediatrician, the pathologist and the general practitioner.

Much work remains to be done. The life cycle of *Toxoplasma* is as yet incompletely understood. Its exact classification is uncertain and the natural mode of transmission is obscure. Adequate epidemiologic studies are lacking. The question of vectors has not been investigated. Future studies will show the extent of the problem of toxoplasmosis. Any attack on the disease will have to be along the lines of prevention, since therapy will have little to offer once the irrevocable destruction of brain and retina has taken place.

PENICILLIN EXCRETORY BLOCKADE

Florey,¹ Rammelkamp² and others have shown that within an hour after penicillin administration by the intravenous route fully 60 per cent of the injected dose is excreted in the urine. By the end of this time the penicillin concentration of the blood stream falls to zero. Frequent reinjections are therefore necessary to maintain an adequate therapeutic concentration in the blood stream. Diodrast, hippuran and other substances that are known to be excreted mainly by the renal tubules exhibit a similar rapidity of elimination, suggesting the probability that, in addition to being filtered through the glomeruli, penicillin is also excreted in large measure by the renal tubules. If so, the rapid urinary loss could be prevented by therapeutic blockade of the tubular excretory function.

A theoretical basis for such blockade is furnished by the well known mutual depression of tubular excretion by competing chemical agents.³ When such substances as diodrast, hippuran, phenol red and other similar derivatives are given simultaneously a manifest reduction in the rate of excretion of all injected substances occurs, presumably because of their competition for elimination through a common mechanism. Rammelkamp and Bradley⁴ of Boston University School of Medicine therefore tested the effects of simultaneous injection of penicillin and diodrast on clinical patients. The rate of renal elimination was first measured after a single control intravenous injection of 5,000 Oxford units of penicillin. Twenty-four hours later the same patients were given a simultaneous intravenous injection of 5,000 Oxford units and 30 cc. of diodrast. The control 60 per cent excretion of penicillin by the end of one hour was reduced to 20 per cent as a result of the simultaneous injection of diodrast. In the control test the initial penicillin titer of the blood serum fell from 0.312 unit per cubic centimeter to practically zero by the end of forty minutes. As a result of diodrast blockade the forty minute reading was 0.039 unit per cubic centimeter. The average control penicillin excretion of all patients was 57.2 per cent of the injected dose by the end of four hours, which was reduced to 32 per cent as a result of diodrast blockade.

Beyer and his associates⁵ of the Department of Pharmacology and Bacteriology, Medical Research Division, Sharp and Dohme, Inc., Glenolden, Pa., have recently tested a second blocking substance, p-aminohippuric acid. This substance was selected because it has remarkably low toxicity. In a typical control test 10,000 Oxford units of penicillin was injected intravenously as a single dose into a nonanesthetized trained dog. In the blockade test p-aminohippuric acid was infused simultaneously with the penicillin. Recovery of penicillin in the urine when p-aminohippuric acid was not administered averaged 78 per cent of the injected dose, falling to a 33 per cent recovery as a result of p-aminohippuric acid blockade. With blockade the plasma concentration does not fall below 0.2 unit per cubic centimeter by the end of two hours, with a two hour zero plasma concentration in the control nonblockade test.

Forty-eight hour experiments were performed on anesthetized dogs, during which both penicillin and p-aminohippuric acid were infused continuously, the infusion rate of the penicillin being 15 units per minute. In the nonblockade control test the plasma titer did not rise above 0.02 unit of penicillin per cubic centimeter during the forty-eight hours. In the blockade test the

titer rarely fell below 0.1 unit per cubic centimeter, a fiftyfold increase in average plasma titer. There appeared to be no pathologic effects attributable to the forty-eight hour combined penicillin blockade therapy. In the opinion of Beyer and his associates the combined intravenous administration of penicillin and p-aminohippuric acid is of sufficient therapeutic promise to warrant clinical trial.

SIMPLIFIED THERAPY OF MENINGITIS

Rammelkamp and Keefer¹ found that penicillin injected intravenously is not excreted into the normal cerebrospinal fluid. From this it has been quite generally concluded that it is necessary to treat cases of meningitis by combined intravenous and intrathecal injections of penicillin. According to Rosenberg and his colleagues² of the U. S. Navy Medical Corps, Great Lakes, Ill., this combined treatment has given prompt and effective clinical results. Nevertheless, in their opinion the necessity for such combined therapy has not been established. It has not yet been shown that intravenously injected penicillin is not extravasated in adequate amounts by inflamed cerebrospinal tissues.

Rosenberg and his associates³ therefore injected 20,000 to 40,000 Oxford units of penicillin intravenously or intramuscularly into each of 8 meningitis patients. From 60 to 140 minutes later they withdrew a sample of spinal fluid from each patient for penicillin assay. They found that, contrary to previous expectation, a considerable amount of penicillin is excreted into the spinal fluid of each meningitis patient. The amounts varied with different patients. The lowest titer was 0.03 Oxford unit per cubic centimeter of spinal fluid and the highest titer 0.35 unit (average titer 0.19 unit).

Rammelkamp and Keefer⁴ found that penicillin in human serum in concentrations as low as 0.019 unit per cubic centimeter produces maximum bactericidal effects against *Streptococcus hemolyticus* and that 0.156 unit per cubic centimeter produces maximum bacteriostasis with *Staphylococcus aureus*. From these data Rosenberg concludes that the excretion (or extravasation) of penicillin into the spinal fluid of meningitis patients after intramuscular or intravenous injection of sufficiently large doses is adequate for the control of meningitis due to susceptible organisms, without the necessity of a supplementary intrathecal injection.

Hac⁵ has recently described a similarly increased extravasation or excretion of subcutaneously injected penicillin into experimentally infected skeletal muscles (*Clostridium welchii*).

THE PUBLIC RELATIONS SURVEY OF CALIFORNIA

In *California and Western Medicine* for July appears the report of a public relations survey made for the California Medical Association by the firm of Foote, Cone & Belding. After several pages in which Mr. John R. Little justifies the survey and commends the association for having expended the necessary \$8,000 to secure it, he turns to the recommendations which result from the survey. This investigation yielded an opinion like that of a similar survey conducted previously by the Opinion Research Corporation for the National Physicians' Committee: the public does not object to prepayment plans. In California it did apparently object to the prepayment plan then being conducted by the California Physicians' Service. Mr. Little stated that a plan must be developed which will cover between 3,000,000 and 5,000,000 people in California and that it must be built on the finest standards of American business. For this purpose he indicated two necessities: (1) a splendid business executive administrator who must be from business and not from medicine or an allied profession and (2) the creation of a new public relations department to deal with the members of the California Medical Association and county medical societies throughout the state, this also to be headed by a layman. Finally, Mr. Little recommended that all councils in the California Medical Association and in the several county societies be divided into three groups responsible respectively for (1) progress of scientific medicine, (2) medical economics and (3) public relations.

The maintenance of medical standards in medical education and medical practice, the observation of medical ethics in medical practice and the maintenance of the personal relationship between doctor and patient, which have long been considered fundamental to the quality of medical care, are ideals understood by physicians. Economists, sociologists, business executives and insurance agencies seem to have had but little sympathy with these ideals in the past. Mr. Little, in his recommendations to the California Medical Association, follows the line long emphasized by Michael Davis, Isadore Falk and others that the profession of physicians demands merely that he practice medicine and that the terms of his practice, the nature of the distribution of medical service and the conditions of the relationship of the doctor to the hospitals, the clinics, the health centers and similar agencies may well be left to economists and business administrators. Exactly what the California Medical Association will do to make Mr. Little's report effective is not yet apparent.

Mr. Little has apparently been endeavoring to define trends, with the point of view that doctors ought to observe trends and go along with them. There are, however, both favorable and unfavorable trends from the point of view of medical practice. Long ago a

1. Rammelkamp, C. H., and Keefer, C. S.: *Am. J. M. Sc.* **205**: 343, 1943.

2. Rosenberg, D. H., and Arling, P. A., to be published.

3. Rosenberg, D. H., and Sylvester, J. C.: *Science* **100**: 132 (Aug. 11) 1944.

4. Rammelkamp, C. H., and Keefer, C. S.: *J. Clin. Investigation* **22**: 423, 1943.

5. Hac, L. R.: *J. Infect. Dis.* **74**: 164, 1944.

medical philosopher urged physicians to observe well the trend of the disease, and if it be upward and toward health, then to aid the trend and go with it toward recovery; but if the trend be downward and toward death, then the physician should interfere so that he may, if possible, reverse the trend. If there were but one way in which the people could secure a high quality of medical service at a low cost, the problem of the medical profession at this time would be exceedingly simple. There are, however, many different approaches to this problem. There is the former technic of the California Physicians' Service and the changed plan. There are similar but in some respects different plans already in effect in other states. There are the technics now being developed by a variety of private insurance agencies in cooperation with large industries. There is the plan of Mr. Henry Kaiser. There is the possibility of compulsory sickness insurance on a county, a state or a national basis. The most important fact that comes out of Mr. Little's survey is that people in California were not satisfied with the California Physicians' Service up to the time of his survey and that changes seemed to be necessary to satisfy the people. Whether these changes when made will be satisfactory will remain, of course, for time and the California Medical Association to determine.

Current Comment

THE RED CROSS MEDICAL COMMITTEE

This week the American Red Cross announced through its new chairman, Mr. Basil O'Connor, the appointment of a special Medical and Health Committee to survey current Red Cross operations of a medical and health character and to recommend plans for the postwar period. The membership of the committee includes:

Dr. Lewis H. Weed, chairman, Washington, D. C., Division of Medical Sciences, National Research Council.

Dr. Felix J. Underwood, vice chairman, Jackson, Miss., president, American Public Health Association.

Dr. George Baehr, New York, director of clinical research, Mount Sinai Hospital.

Dr. Wilburt C. Davison, Durham, N. C., dean and professor of pediatrics, Duke University School of Medicine.

Dr. Morris Fishbein, Chicago, Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Dr. Alan Gregg, New York, director of the medical sciences, Rockefeller Foundation.

Major Gen. Norman T. Kirk, Washington, D. C., Surgeon General of the U. S. Army.

Dr. Frank H. Lahey, Boston, national chairman of the directing board, Procurement and Assignment Service for Physicians, Dentists, Veterinarians, Nurses and Sanitary Engineers, Lahey Clinic.

Dr. Roger I. Lee, Boston, President-Elect, American Medical Association.

Vice Admiral Ross T. McIntire, Washington, D. C., Surgeon General of the U. S. Navy.

Dr. Thomas Parran, Washington, D. C., Surgeon General of the U. S. Public Health Service.

Dr. Henry R. Viets, Boston, will act as secretary of the committee. In making his announcement Mr. O'Connor said:

Medical and health problems touch virtually every aspect of Red Cross activities, whether in terms of disaster relief, nursing, accident prevention, nutrition or blood donations. Because of this vital relationship to the general Red Cross program, I have asked eleven prominent medical and health experts to serve as a special committee to survey what we are doing currently, analyze the results achieved and give me a blueprint of possible Red Cross activities in these fields in the postwar period. The group appointed was chosen because of their familiarity with operations of the American Red Cross in the medical and health fields.

The medical profession may await with interest the reports of this group. The blood donor service, the nursing services, the nutrition, first aid, disaster relief activities, the home services and those functions dealing with medical supplies all come closely to problems that affect the medical profession. Chairman Basil O'Connor merits commendation for having enlisted medical interest and sought competent advice in developing the innumerable medical activities of the American Red Cross.

WILLIAM GILBERT—PHYSICIAN TO QUEEN ELIZABETH

William Gilbert, who was physician to Queen Elizabeth and James I of England, was born about four hundred years ago. The place of Gilbert in the medical world has been described recently by Sir Walter Langdon-Brown.¹ Gilbert's influence on the medical profession of his day was profound: he insisted on observation and experiment, and he scorned reliance on mere authority; he demonstrated hatred for sham and quackery and was far in advance of his times in condemning some of the extraordinary prescriptions of the day. He recognized the value of iron "as a fine powder steeped in the 'sharpest vinegar' and dried, for the treatment of anemia." While remaining prominent in medicine, Gilbert demonstrated a notable versatility. His masterpiece, "De magnete," has become recognized as a great pioneer work on magnetic and electrical experiment; he has been called "the father of the sciences of geomagnetism and electricity."²

INTRANASAL VACCINATION FOR COLDS

Studies on the possible value of bacterial vaccines for the prophylaxis of the common cold continue. Now Cowan and Diehl¹ report observations on three groups of students given different types of "cold" vaccine administered intranasally by atomizer and one comparable control group similarly receiving a sterile isotonic solution of sodium chloride containing merthiolate 1:20,000 and just enough fluorescence to render the solution faintly colored and turbid. Significant differences in severity or duration of colds or in frequency of complications between the groups were not observed. Thus this carefully controlled study of intranasal vaccination fails to furnish any evidence of the value of intranasal vaccination for colds.

MEDICINE AND THE WAR

ARMY

AVIATION MEDICAL EXAMINERS

Graduating exercises were held at the School of Aviation Medicine, Randolph Field, Texas, on July 26, following completion of the course for aviation medical examiners. The list of medical corps students graduating follows:

ALABAMA

John R. Chapman, Captain, Good Water

CALIFORNIA

Albert N. Anton, Captain, Los Angeles
George E. Beckerman, Captain, Santa Monica
Lewis T. Bullock, Major, Los Angeles
Rev. N. Carr, 1st Lieut., San Mateo
Lee D. Fulton, Captain, San Francisco
Alfred E. Gardner, 1st Lieut., Ignacio
Robert W. King, Captain, San Jose
Charles I. Morris, Captain, San Francisco
Seymour A. Spungin, Captain, Los Angeles
Ernest M. Stanton, 1st Lieut., Santa Monica
Orville O. Witherbee, Captain, Los Angeles

COLORADO

Orin M. Stout, Major, Denver

DISTRICT OF COLUMBIA

Francis T. Coleman, Major, Washington
Abraham B. Mineosky, 1st Lieut., Washington

FLORIDA

Francis T. Holland, Captain, Tallahassee
John L. Jennings Jr., Captain, Boca Grande
James E. Kendrick, 1st Lieut., Homestead

GEORGIA

Ottis E. Hanes, Captain, Atlanta
James M. Sutton Jr., Major, Sylvestor

ILLINOIS

John I. Brewer, Lieut. Col., Chicago
George J. Cooper, Captain, Chicago
Philip Lerner, Captain, Chicago
Clifford H. Peters, Captain, River Forest
William C. Scott, Captain, Elkhart
Carol van der Heide, Captain, Chicago

INDIANA

John W. Humphreys, Major, Vincennes
Edward C. Lidikav Jr., Captain, Logansport
Thomas O. Middleton, 1st Lieut., Vincennes
Robert H. Williams, Captain, Anderson

IOWA

Edward F. Anderson, Captain, Dubuque
Walford D. Marrs, Captain, Tabor

KANSAS

Shirley E. Clark, 1st Lieut., Rush Center
Arnold H. Janzen, Captain, Butler
Darwin C. Reed, Captain, Wichita
Eldee L. Schneider, 1st Lieut., Dodge City

KENTUCKY

Robert C. Bnteman, Captain, Springfield
William C. Busehemyer, Captain, Louisville

LOUISIANA

William H. Byrne, Captain, New Orleans
Joseph D. Kinn, Captain, New Orleans
William T. Yates, 1st Lieut., Baton Rouge

MAINE

Paul V. Davis, Major, Bridgton

MASSACHUSETTS

Donald V. Baker Jr., 1st Lieut., Uxbridge
John K. Brines, Captain, Wellesley
Henry C. Thacher, Captain, Yarmouth Port

MICHIGAN

Thomas E. Gibson, Major, Ithaca
Warren V. Hinshaw, Captain, Adrian

Alfred E. Thomas Jr., Captain, Detroit

MINNESOTA

Carl L. Lundell, 1st Lieut., Cloquet

MISSISSIPPI

Robert G. Head, Captain, Menard

MISSOURI

Francis O. Trotter Jr., 1st Lieut., Kansas City

NEBRASKA

Verne H. Alder, Captain, Omaha
Robert J. Morgan, 1st Lieut., Alliance
Claude W. Otto, 1st Lieut., Aurora
Ward A. Peterson, Captain, Omaha
Alvin F. Sonnenberg, Captain, Lincoln
Lavern D. Sprague, 1st Lieut., Omaha

NEW HAMPSHIRE

Frank D. Fikavich, Major, Troy

NEW JERSEY

Joseph A. Buchignani, Captain, Newark
Maurice P. Charnock, Major, Trenton
Charles Kieggerrman, 1st Lieut., Atlantic City

NEW MEXICO

Daniel H. Cahoon, Captain, Roswell

NEW YORK

Louis F. Bishop Jr., Lieut. Col., New York
Homer T. R. Bull, Captain, Genesee
Alvin M. Cahon, Captain, New York
Ward V. Ceilly, Major, Brooklyn
Clyde K. Conrad, Major, Chapin
Cornelius J. Dwyer Jr., Captain, Brooklyn
Samuel Feinberg, Captain, Port Jefferson
Allan L. Friedlich Jr., 1st Lieut., New York
Jack H. Galen, 1st Lieut., Brooklyn
Roger H. George, Captain, Verona
Bernard C. Glueck Jr., Ossining
George Goldstein, Captain, Brooklyn
Basel C. Gray, Captain, New Berlin
Max S. Kongsberg, Captain, New York
Sidney Kreinin, Major, Brooklyn
Irving L. Leff, Captain, Kew Gardens
William W. Pierce, Major, Grapport
Bradley W. Prior, 1st Lieut., Buffalo
Shepard Quimby, Major, Hamburg
John R. Roche, Major, Laurelton
Irving M. Rollins, 1st Lieut., Forest Hills
Robert S. Siffert, 1st Lieut., Brooklyn
Willard L. Smith, 1st Lieut., White Plains
John M. Tortora, Captain, Brooklyn

NORTH CAROLINA

Thomas E. Andes, Captain, Lenoirville
Henry Luhn, Captain, Fairmont
William C. Parks, 1st Lieut., High Point

OHIO

Alfred W. Erb, Captain, Piqua
Wilham M. Garrett, Captain, Frankfort
Gordon H. Hammill, Captain, Euclid
John A. Kramer, Captain, Columbus
Thomas E. Miller, Captain, Iron ton
Frank D. Noy, Captain, Euclid
Samuel M. Schall, 1st Lieut., Toledo
Carl F. Schilling, 1st Lieut., Cincinnati
Frederick S. Spiegel, Captain, Cincinnati
Ralph W. Tapper, 1st Lieut., Dayton
Robert E. Tschantz, Captain, Hartsville

The following officers are in the Colombian army:

Pafael Arturo Bero, Captain,
Luis A. Gomez, Major

In addition there was one member of the Medical Corps of the Chilean Air Force, Lieut. Col. Luis C. Vivian

OKLAHOMA

Hillard F. Denyer, Major, Chandler
James W. Downey, 1st Lieut., Chickasha
Ralph W. Morton, Captain, Sulphur
Leonidas W. Payne, Major, Pauls Valley
Harold B. Witten, Captain, Harral

OREGON

Richard W. Leong, 1st Lieut., Portland

PENNSYLVANIA

Edward R. Deverson, Captain, Pittsburgh
Milton H. Gruditor, Captain, Conansburg
Newton W. Hershner Jr., Captain, Mechanicsburg
John M. Hieckes, 1st Lieut., Glassport
Ernie C. Jameson Jr., Captain, Philadelphia
Thaddeus A. Nighborowicz, 1st Lieut., Gallitzien
Frank T. O'Brien, 1st Lieut., Seranton
John J. O'Keefe, Major, Bith Cinnnyd
Lamil E. Reiss Jr., Captain, Pittsburgh
Henry Rothkopf, Captain, Philadelphia
William L. Schaefer Jr., 1st Lieut., Middletown
William I. Westcott, Captain, Doylestown

TEXAS

George W. Berry, 1st Lieut., San Antonio
Richard E. Nicholson, 1st Lieut., Dallas
Fred P. Robbins, Captain, Randolph Field
Gus C. Yelderman, Major, Rosenberg

VIRGINIA

Charles R. Mills, Captain, Bristol
Hugo A. Sacchet, 1st Lieut., Clifton Forge

WASHINGTON

Ralph M. deBit, Captain, Kennewick

WEST VIRGINIA

James R. Goolsen, 1st Lieut., Davis

WISCONSIN

Richard D. Champney, Captain, Milwaukee
William B. Cheeseman, 1st Lieut., Madison
Edward Zamil, Captain, Milwaukee

ARMY AWARDS AND COMMENDATIONS

Colonel Clifford V. Morgan

The Legion of Merit award was recently presented to Col. Clifford V. Morgan of Washington, D. C., for "services in the Office of the Undersecretary of War from September 1940 to March 1942. As chief of the Commodities Division, Resources Branch, and its representative in the Army and Navy Munitions Board, he was charged with the responsibility of determining the needs of the armed services and of essential industries for strategic, critical and essential materials required for the vastly expanded production program, and, according to the degree of their scarcity, to initiate measures designed to insure their proper and most efficient allocation. As the emergency became more acute he, because of his comprehensive grasp of the entire munitions problem, his executive ability, powers of perception and analysis, and his great tact in securing adjustments with the numerous boards and committees of other agencies of the government and with authorized representatives of industry, contributed materially to insuring supplies of the vitally needed materials without which the expanded war production program could not have been accomplished." Dr. Morgan graduated from the University of Nebraska College of Medicine, Omaha, in 1927 and has been in the service since August 1928.

Major Edward A. Kelly

The Silver Star was recently awarded to Major Edward A. Kelly, formerly of Washington, D. C. The citation states that Major Kelly, who was assigned to the ship's hospital, "distinguished himself when, after the ship had received a direct hit by an aerial bomb, he administered medical aid to wounded personnel under risk to his own life. The bomb had smashed the ship's dispensary, and he engaged in giving aid to the wounded on the decks despite confusion and pandemonium caused by the explosion and the resulting fire, smoke and escaping steam. As the ship began to list he carried many wounded men from the starboard to the port side, inflated their life belts and lowered them into the water by means of ropes.

He continued to work until practically all living personnel were evacuated. Major Kelly was taken into a lifeboat after four hours in the water and, in the lifeboat rendered medical aid to wounded there and helped load them aboard a rescue ship. When he was taken on the rescue ship he resumed the task of giving medical aid and worked steadily until all the wounded were cared for, eleven hours after the troopship had been hit. His absolute devotion to duty in the face of danger and under extremely difficult conditions are consonant with the fine traditions of the American military service." Dr. Kelly graduated from Georgetown University School of Medicine, Washington, D. C., in 1934 and entered the service June 20, 1942.

BRUNS GENERAL HOSPITAL BECOMES
TUBERCULOSIS CENTER

The Bruns General Hospital, Santa Fe, N. M., under the command of Brig. Gen. Larry B. McAfee, has been designated as an army center for the treatment of tuberculosis. The hospital is specially staffed with tuberculosis experts and utilizes the most modern equipment and methods of treatment. Bruns General Hospital was named in honor of Col. Earl Harvey Bruns, who was one of the most distinguished phthisiologists in the history of the Army. As chief of medical service at Fitzsimons General Hospital, Denver, which is also an army tuberculosis center, he introduced much of the therapeutic practice now in effect there and trained many officers in the principles of tuberculosis control.

APPOINTED POST SURGEON

Major Nicholas R. Locascio, formerly of New York City, has been appointed post surgeon and commanding officer of the Army Station Hospital at Pine Camp, New York, succeeding Col. Dunlap P. Penhallow. In active service in the Reserve Officers Corps since 1931, Dr. Locascio reported for active duty June 2, 1941. He entered the service with the rank of captain in 1935 and was promoted to major in 1942.

MISCELLANEOUS

NEUROPSYCHIATRY IN THE
JAPANESE ARMY

Interview at the Japanese Prison Camp, Blue
Beach, Cape Gloucester, New Britain,
with Dr. Otsuko Hideo

Lieutenant Commander T. E. Newell (MC), U.S.N.R.

(Interpreter, 2d Lieut. Harry T. Foote, U.S.M.C.R., Japanese
Interpreter Section, Division Intelligence Section,
First Marine Division)

Dr. Otsuko is 31 years of age, intelligent, cooperative and congenial. His home is in Tokyo, Japan, where he graduated from medical school at the Imperial University in 1940. Following his four year course in medicine he interned one year in a civilian hospital. He then practiced general medicine in civil life for one and one-half years in Tokyo. I explained that I wished to get information about methods used in psychiatry in the Japanese military forces. He was cooperative in every way.

He has been in military service three years in the army, the first nine months in Japan, then in the Philippines and Rabaul. He spent one year in a military base hospital. He went to Rabaul during January 1943 and for six months was assigned to duty in a field hospital. In the Philippines and Rabaul he was attached to the 1st battalion, 141st Infantry Regiment, but since then he has been in smaller field hospitals. His recent duty has been at Borgan Bay. During battles he has always worked in field hospitals and not on the front lines.

His knowledge of military medicine seemed good and he has apparently had first hand knowledge of subjects on which he was interrogated. His answers were usually prompt, but at times he would think a moment or two before answering to be sure he was right. Very few of the Japanese prisoners with him have seemed reluctant to give us any information desired. They have careful screening of mentally unstable men in Japan

before they are sent to foreign duty. This is carried out by trained psychiatrists. They may not be specialists in psychiatry but they usually have at least the rank of major.

Three to 7 per cent of military men are eliminated in Japan because of mental instability. They have "very few neurotics, almost none." He admits some, maybe 1 in 100 or less. As the interview progressed, it was clear that it was a problem with the Japanese as it is with other people.

Disposition of war neurosis cases in the Japanese army is quite similar to that in the German armies in the last war. They are segregated immediately to protect and help the patients themselves and also to prevent a bad influence on their comrades. They try to keep them on their duty, but if they are too nervous they are sent back to field hospitals in the immediate vicinity. They are treated by sedatives sufficient to give them rest and sleep. They are held here for three weeks to one month, at least ten days and, at most, two or three months before being sent back to duty or evacuated. From places like Borgan Bay or Cape Gloucester patients needing further care were sent to a hospital at Rabaul. Dr. Otsuko said these measures are taken to prevent the patients from getting "serious" or "very ill." The treatment and the results vary greatly. When good recovery occurs the men are returned as soon as possible but not usually in less than ten days. Others are retained at field and battalion hospitals and are given sedatives as needed and occupational treatment, which consists of light duty, policing hospital areas and such entertainment as can be had. They are given very considerate attention and "no work of the brain." In foreign duty if they do not recover in about three months they are returned to Tokyo military hospitals and put in what are similar to our "N. P." wards.

The doctor wrote in my note book, in English, the term they use for war neurosis, "krieg neurosis," and I assumed it to be named for them by the Germans. This diagnosis is not considered a very complimentary label for a soldier returning as

unfit for further duty, it probably being similar to the term "fear state" advocated by the Australian medical authorities. These men are treated as all war casualties in Japan as "unfortunate individuals" and the patients feel likewise, whether their disability is mental or physical. In rural and suburban areas the attitude is the same as in large cities. The psychoneurotics in Japan are considered as honorably ill as those with malaria or other such diseases. He said "We are good to our war casualties at home."

All military units are taught and lectured to in regard to defending themselves against mental difficulties as they are against physical diseases. Dr. Otsuko says it is a military policy for the commanding officers to note any unusual acts of the men and try to direct their thinking and conduct on the spot. His impression is that there is usually good cooperation in this regard, and results are said to be good. Dr. Otsuko would not admit at any time that these patients are dealt with in a harsh manner. These methods of observation and early treatment of cases are followed out in field hospitals also.

Thirty per cent of these casualties are returned to duty in the field or from field hospitals. This includes those returning to duty from field hospitals and probably from advanced base hospitals at places like Rabaul. Five to 7 per cent go back to Tokyo; the remainder are held for noncombat duty. This non-combat group comprises about 64 per cent of the total. These figures indicate that the average soldier can hope very little for a gain to be derived from developing a neurosis.

Diseased and run down men succumb to psychoneurosis more readily than healthy men. Dr. Otsuko thinks that the greater the hazards of war, the greater the incidence of mental diseases. Men who have long been in combat operations are more often affected than well seasoned troops with less severe war experiences.

They have trained psychiatrists who go from front to front and from hospital to hospital to take into consideration mental problems of personnel in every phase of warfare from front lines back to the advanced base hospitals.

Men discharged from military service because of war neurosis are put back into civil life at farms or other home jobs available and suitable. Special efforts are being made to rehabilitate these men and get them into suitable occupations.

After the interview the doctor asked that he be given some real nice biscuits and some real butter. He has been allowed special privileges over the other prisoners and to eat apart also. He was given some special foods the boys had on hand but unfortunately the boys had no biscuits.

NEW MEDICAL MEMBERS OF STAFF FOR OFFICE OF VOCATIONAL REHABILITATION

The appointments of Dr. Victor H. Vogel, Surgeon, U. S. Public Health Service, as consultant in psychiatry and Dr. Mark E. Gann, Surgeon (R), U. S. Public Health Service, as assistant regional representative are announced by Michael J. Shortley, director, Office of Vocational Rehabilitation, Federal Security Agency, effective September 1.

As a member of the staff of the physical restoration section of the federal office, Dr. Vogel's activities as consultant in psychiatry will include the organization of programs for the rehabilitation of persons with psychiatric disabilities and mental hygiene programs for all handicapped persons who are clients of state rehabilitation agencies. The federal-state grant-in-aid program for the vocational rehabilitation of civilian disabled persons provides for the inclusion of psychiatric diagnosis and treatment, and Dr. Vogel's consultative services will be available to vocational rehabilitation agencies and agencies for the blind in all states, the District of Columbia, Puerto Rico and Hawaii.

Dr. Vogel is a graduate of the University of Colorado Medical School, 1929. He was granted the degree of master of public health at the Johns Hopkins University in 1940 and received postgraduate training in psychiatry at the Colorado Psychopathic Hospital in 1937-1938, and at the Johns Hopkins Medical School in 1939-1940. He is a certified specialist of the National Board of Neurology and Psychiatry and a fellow of the American Psychiatric Association. Dr. Vogel served as

assistant chief, Mental Hygiene Division, and mental hygiene consultant to the states, U. S. Public Health Service, 1940-1942.

Dr. Gann has been assigned to the San Francisco office to assist the state rehabilitation agencies in the inauguration of physical restoration services and to aid in the interpretation of the vocational rehabilitation program to cooperating organizations and professional groups. His services as a consulting medical officer will be available to all states in the western area. Dr. Gann is a graduate of the Johns Hopkins School of Medicine, 1933. He received training in surgery at the Sinai Hospital, Baltimore, in 1933-1938 and engaged in the private practice of general surgery in Baltimore from 1938 to 1943. Prior to his assignment to the Office of Vocational Rehabilitation, Dr. Gann's period of active duty with the U. S. Public Health Service included industrial surgery and participation in the medical care project in the Mobile, Ala., war housing clinics.

PATHOLOGISTS PRESENT MILITARY PROGRAM

It is planned to devote a considerable portion of the 1945 meeting of the American Society of Clinical Pathologists to subjects of primary interest to laboratory officers in the armed forces of the United States, i. e., to military pathology. While the date and place of the meetings are not yet definitely decided, it will most likely be in Chicago about the first week of June.

It is the desire of the program committee that laboratory officers working in military hospitals participate actively in this program. The committee therefore requests that materials which would be of interest for such a program be kept in mind.

If within the course of the next months such materials or data of interest in military laboratory work come to the attention of these laboratory officers and they desire to present them at the 1945 A. S. C. P. meeting, they should communicate directly with Dr. A. S. Giordano, chairman of the Program Committee, American Society of Clinical Pathologists, 531 North Main Street, South Bend, Ind.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, September 30, page 307)

CALIFORNIA

Stanford University Hospitals, San Francisco. Capacity, 372; admissions, 9,588. Dr. Anthony J. J. Rourke, Superintendent (resident—surgery, obstetrics and gynecology, anesthesia, psychiatry, medicine, nose and throat).

MICHIGAN

Eloise Hospital and Infirmary, Eloise. Capacity, 6,432; admissions, 7,095. Dr. Charles J. Smyth, Medical Director (3 residents—medicine, November 1).

NEW YORK

Bronx Hospital, New York City. Capacity, 389; admissions, 8,075. Mr. William B. Seltzer, Superintendent (resident—surgery). Mother Cabrini Memorial Hospital, New York City. Capacity, 295; admissions, 2,976. Mother Corinna, Superior (interns).

WASHINGTON

St. Luke's Hospital, Spokane. Capacity, 236; admissions, 4,699. Mr. Gordon W. Gilbert, Administrator (interns).

WEST VIRGINIA

Kanawha Valley Hospital, Charleston. Capacity, 165; admissions, 4,414. Dr. G. B. Capitol, President (1 intern, 1 resident—mixed service). St. Mary's Hospital, Clarksburg. Capacity, 192; admissions, 4,201. Sister M. de Sales, Administrator (2 residents—mixed service).

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Mayo General Hospital, Galesburg, Ill.: High Blood Pressure, Drs. Adrien H. P. E. Verbruggen and Louis N. Katz, October 18.

Camp Ellis, Camp Ellis, Ill.: Diseases of the Intestinal Tract, Drs. Warren H. Cole and Michael H. Streicher, October 18.

Chanute Field, Rantoul, Ill.: Thrombosis, Thrombophlebitis and Anticoagulants, Col. Irving S. Wright, October 18.

ORGANIZATION SECTION

WASHINGTON LETTER (From a Special Correspondent)

Oct. 2, 1944.

Intensified Venereal Disease Control During Demobilization Discussed

Action of the War Advertising Council in withdrawing its support from the Antivenereal Disease Campaign of the U. S. Public Health Service, because of its "highly controversial nature" and evidence that the drive was "repugnant to many Catholic organizations," received no direct comment from the National Venereal Disease Committee today. The Federal Security Agency, however, has revealed that the campaign has just been explored again fully, with a Catholic committeeman in attendance. Indications were that efforts against the disease are to be intensified in spite of this negative step by one of the important supporting organizations. At the second meeting of the National Venereal Disease Committee, just completed, plans were further explored to keep the disease in check during the demobilization period. The meeting dealt primarily with steps to be taken to reduce the estimated 5,000,000 civilian venereal disease cases and to cut infection rates among military personnel.

The meeting dealt comprehensively with the problem, Lieut. Col. Thomas H. Sternberg discussing the Army aspect, Commander S. H. Schwartz that of the Navy; Dr. J. R. Heller, Bethesda, Md., assistant surgeon of the Division of Venereal Diseases of the U. S. Public Health Service, medical developments; A. E. Kimberling, Louisville, Ky., chief of police, law enforcement technics; Chief of Police Fred Roff of Morristown, N. Y., views of the International Association of Chiefs of Police; Rt. Rev. Howard J. Carroll, assistant general secretary of the National Catholic Welfare Conference, outlining religious aspects of the venereal disease problem, and Dr. William F. Snow, New York, of the American Social Hygiene Association, stressing the need of public education.

La Guardia Describes New York City Health Problems

Mayor Fiorella La Guardia was to describe health problems of New York City when he appeared as a witness this week before the Kelley Committee investigating Aid to the Physically Handicapped, slated to continue through October 2, 3 and 4 at the Federal Court House in New York. The hearing promised many notable developments, according to the chairman, Congressman Augustine B. Kelley of Pennsylvania, who announced that other witnesses include Miss Helen Keller; Arde Bulova, who has endowed a school to train disabled veterans in watch making; Dr. Ernest Stebbins, New York City commissioner of health; Mrs. Anna Rosenberg of the War Manpower Commission, and Dr. Peter Irving, secretary of the Medical Society of the State of New York. The committee moves on to Pittsburgh on October 17 and 18, when industrial health will be investigated. Also called are Robert Lansdale, commissioner, New York State Department of Social Welfare; G. Samuel Bohlin, chief, Bureau of Vocational Rehabilitation; Holland Hudson, secretary, National Council on Rehabilitation; Robert P. Lane, director, Welfare Council of New York City; Charles E. Hoppin, New York State Veterans Commission; Clarence D. O'Connor, superintendent, Lexington School for the Deaf; Michael J. Murphy, New York State Department of Labor; Dr. Herbert J. Stack, director, Center of Safety Education, New York University; Edward Hochhauser, executive director, Committee for the Care of Jewish Tuberculous, Inc.; Dr. Haven Emerson, DeLamar Institute College of Physicians and Surgeons, Columbia University; Miss Ann Lehman, consultant on the handicapped, United States Employment Service; Col. John Smith Jr., director, Institute for Crippled and Disabled; Miss Frances E. Moscrip, inspector, Classes for the Blind, Board of Education, Brooklyn.

Need of Safeguarding War Workers' Health Emphasized

The War Manpower Commission proposes to continue all possible efforts to safeguard the health of war workers as a means of cutting down absenteeism and increasing labor productivity, War Manpower Commission Chairman Paul V. McNutt emphasizes. He declared that there will be no letdown in War Manpower Commission cooperation in the United States Public Health Service program for war workers. Health standards must be maintained in all war plants engaged in producing equipment urgently needed by the Army and Navy, he said.

Evaluating accomplishments in the joint program up to date, he said that investigations had been conducted at 11,000 war plants in twenty-eight states. These had resulted in many recommendations for correction of poor health conditions affecting war workers. On March 1 he reported 162 projects for new hospitals, 409 for hospital additions and 377 for nurses' homes and training facilities; 254 projects for health centers had been investigated and recommended to the Federal Works Agency. Manpower utilization consultants in the field, he said, would be held responsible for reporting to the U. S. P. H. S. on safety and health programs in all war plants, particularly those of "must" plants. A simplified guide helps consultants to spot health problems. A thumb rule approach is given to such safety and health matters as accident and illness prevention through programs of industrial hygiene, hospital and health center assistance, inplant medical and dental services, promotion of sanitary services, mosquito control and anti-venereal disease campaigns.

MEDICAL ECONOMIC ABSTRACTS

INDIANA PREPARES PREPAYMENT PLAN

The 1943 meeting of the house of delegates of the Indiana State Medical Association appointed a permanent study committee on health insurance, which submits its first report for the 1944 meeting of the house of delegates.

The committee "has arrived at the conclusion that the best present solution is the adoption of a state medical association sponsored plan for prepayment for medical service."

Owing to deficiencies in the nonprofit statutes of Indiana and the lack of a special enabling act, "it will undoubtedly be necessary to organize under the insurance statutes of the state either a mutual or stock insurance company or association in order to carry out the recommended proposed program."

"The plan proposed by your committee would provide:

1. For all professional medical, surgical and obstetric services while the patient occupies a ward or semiprivate hospital bed, including anesthesia, x-ray, laboratory and electrocardiographic services.
2. Emergency surgical services in connection with nonhospitalized injuries for the first twenty-four hours.

"These services will be subjected to the following limitations:

1. "Ten month waiting period for obstetric cases.
2. "No obstetric benefits unless family is enrolled.
3. "X-ray service limited to \$15 in any one year.
4. "Twenty-one days of medical care in any one year."

Joint arrangements are contemplated with the Blue Cross Hospital service of Indiana for a joint enrolment and subscriber relations.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Annual Meeting to Be Held in May.—The annual session of the California Medical Association will be held in Los Angeles, May 6-7, 1945. Tentatively the Hotel Biltmore has been selected as the hotel headquarters.

Two Cases of Leprosy.—California's Health recently reported that 2 persons suffering from leprosy were investigated during June. It was determined that both persons, who had at some time been patients in the U. S. Marine Hospital (National Leprosarium) at Carville, La., are suffering from the disease in an inactive form.

Fund for Needy Physicians.—The Los Angeles County Physicians' Aid Association, which has been conducting a campaign to raise \$250,000 to assist unfortunate physicians, announced recently that the \$50,000 mark had been reached. The association is a nonprofit corporation and is intended to aid needy physicians of the Los Angeles County Medical Association.

Memorial Plans for Founders of Moore-White Clinic.—When six members of the Moore-White Clinic, Los Angeles, return from military service, plans will be launched to establish a foundation for research and to perpetuate the activities of the clinic. The plans include the construction of a new building in memory of the founders, Drs. Melvin L. Moore, Edward C. Moore and Percival G. White. The last survivor of the founders' group, Dr. Edward Moore, died July 10.

Practical Psychotherapy.—A course of eight lectures in practical psychotherapy was opened on Monday, October 2, at Mount Zion Hospital, San Francisco. The course, which will deal primarily with the treatment of neuröses and mild personality problems, will be conducted by Dr. Jacob S. Kasanin, director of the department of psychiatry at the Mount Zion Hospital. The course will be open to senior medical students of the University of California Medical School and Stanford University School of Medicine, the interns and residents in various San Francisco hospitals and public health service and medical officers of the Army and Navy.

ILLINOIS

Chicago

Commander Coggeshall to Address Joint Meeting.—Comdr. Lowell T. Coggeshall (MC) will address a joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine, October 23, at the Palmer House. His subject will be "Current and Postwar Aspects of Tropical Disease Problems."

Memorial to Dr. Gifford.—On October 12 a memorial convocation for Dr. Sanford R. Gifford, professor and chairman of the department of ophthalmology at Northwestern University Medical School, will be held at Thorne Hall on the downtown campus of Northwestern University at 4:30. Dr. Irving S. Cutter will preside at the convocation and Anan Raymond, LL.B., will speak.

Dr. Marrazzi Goes to Wayne University.—Dr. Amedeo S. Marrazzi has resigned as professor and head of the department of pharmacology, Loyola University School of Medicine, effective November 15, to accept a similar position at Wayne University College of Medicine, Detroit. Dr. Marrazzi graduated at the Bellevue Hospital Medical College in 1928 and has been identified with Loyola University since Sept. 1, 1943.

Personal.—Dr. Orlen J. Johnson, since August 1941 assistant secretary, Council on Industrial Health of the American Medical Association, has resigned to enter a residency in surgery at St. Luke's Hospital, effective September 30. Dr. Johnson, who graduated at the University of Michigan Medical School, Ann Arbor, in 1930, came to the American Medical Association from a position as plant physician of the Chrysler Corporation, Detroit.

MAINE

1945 Session of Maine Association.—The ninety-second annual session of the Maine Medical Association will be held at the Poland Spring House, Poland Spring, June 24-26, 1945.

MASSACHUSETTS

Women Eligible for Harvard Medical School.—On September 25 the board of overseers of Harvard College, Cambridge, approved a recommendation of the faculty of Harvard Medical School, Boston, that women students be hereafter eligible for admission. The recommendation had been previously approved by the Harvard Corporation and will become effective for students entering the school in the fall of 1945. The Harvard Medical School was opened in 1782. The average enrolment is slightly over 500 students.

MICHIGAN

Special Society Election.—Dr. Frank R. Menagh, Henry Ford Hospital, Detroit, is president of the Detroit Dermatological Society and Dr. Clarence E. Reyner, also of the Ford Hospital, is secretary-treasurer.

Personal.—Dr. Warren Bartlett Crane, Kalamazoo, has returned to private practice after almost three years in military service.—John F. Norton, Ph.D., was elected president of the Kalamazoo Tuberculosis Association August 17 to succeed Dr. Benjamin A. Shepard, who resigned because of ill health.—Dr. Earl F. Lutz, Detroit, has been promoted to associate medical consultant of General Motors. Dr. Lutz, who has served as chief plant physician at the Detroit Diesel Engine Division of General Motors since 1938, will work with Dr. Clarence D. Selby, Detroit, the corporation's medical consultant, and will direct his special attention to the medical aspects of the employment of war veterans.

MISSOURI

Personal.—Dr. Charles A. Brasher, assistant superintendent of the Missouri State Sanatorium at Mount Vernon, has been named superintendent, succeeding Dr. Jesse A. Stocker.—Dr. Lloyd L. Tate has been named health and hygiene director of the St. Louis public schools.

Medical Forum.—On September 20 the 1944-1945 Jackson County Health Forum opened its regular session with a talk by Dr. Arnold S. Jackson, Madison, Wis., on "Worry and Nervous Tension." Other speakers in the series will include:

Dr. Walter C. Alvarez, Rochester, Minn., What Makes Your Stomach Ache? October 18.
Dr. Karl A. Menninger, Topeka, Kan., Psychiatry In the War and After the War, November 15.
Dr. Elliott P. Joslin, Boston, New Discoveries and Management of Diabetes, January 17.
Dr. Alton Ochsner, New Orleans, Varicose Veins—Something Can Be Done About Them, February 21.
Lieut. Col. Philip Lewin, M. C., Backache, Injuries and Sprains, March 21.
Dr. Morris Fishbein, Editor of THE JOURNAL, Chicago, Infantile Paralysis, April 18.

NEW YORK

Medical Broadcasting.—The 1944-1945 broadcasting program of the Medical Society of the County of Monroe opened September 9 over the facilities of broadcasting station WHAM. This is the society's fourteenth season of broadcasting, and the opening broadcast was number 552 in the series. The society claims that its broadcast is among the oldest continuously produced medical broadcasts and is identified on the air as "Rochester's Medical Broadcast."

Changes in State Health Department.—Dr. Elizabeth M. Gardiner, Albany, director of the division of maternity, infancy and child hygiene, retired from state service effective August 31. Dr. Gardiner was director of the division of child welfare in the Rhode Island Department of Health from 1919 until 1923, when she joined the New York State Department of Health staff, serving first as associate director of the division of maternity, infancy and child hygiene and after 1926 as director. Jane E. Dale, Ph.D., has been appointed provisionally to the position of senior nutritionist in the state department of health, serving as supervising head of the nutrition bureau within the division of maternity, infancy and child hygiene.

New York City

The Gross Memorial Lecture.—Dr. Leo Loewe, New York, will deliver the seventh annual Louis Gross Memorial Lecture at the Jewish General Hospital, Montreal, October 25, on "Further Observations on the Combined Use of Penicillin and Heparin in the Treatment of Subacute Bacterial Endocarditis."

Meeting of Anesthetists.—The principal speaker at the meeting of the American Society of Anesthetists at the New York Academy of Medicine, October 12, will be Dr. Carl F.

Schmidt, professor of pharmacology, University of Pennsylvania School of Medicine, Philadelphia. Dr. Schmidt's subject will be "The Newer Concepts of Respiratory Control."

Hospital Flooded.—Three substreet floors of the Reconstruction Hospital were flooded September 10, causing damage estimated at \$100,000 to medical supplies and irreplaceable therapeutic equipment. The flood was caused by a break in the main shortly before midnight, September 9, but the valve controlling the flow of water was not located until sixteen hours later. The New York Times stated that at the height of the flood 40 feet of water inundated the three floors.

Course for Professional Workers.—"Child Health and the Classroom Teacher" is the theme of a course for teachers and professional workers which opened October 4 and will continue weekly until January 24. Dr. Michael Antell, health officer of the Washington Heights-Riverside Health District, is in charge of the course and the sessions are being held at the Washington Heights-Riverside Health Center of the city department of health. It is sponsored by the New York Tuberculosis and Health Association.

Louis Livingston Seaman Fund.—The New York Academy of Medicine announces the availability of the Louis Livingston Seaman Fund to further research in bacteriology and sanitary science. One thousand dollars is available for assignment in 1944. This fund has been made possible by the terms of the will of the late Dr. Louis Livingston Seaman and is administered by the committee of the academy. The fund will be expended only in grants in aid for investigation or scholarships for research in bacteriology or sanitary science and may be made for the securing of technical help, aid in publishing original work and the purchase of necessary books or apparatus. Applications will be received either from institutions or from individuals up to November 1. Communications should be addressed to Dr. Wilson G. Smillie, chairman of the fund, 1300 York Avenue, New York 21.

Mayor's Health Plan Incorporated.—Incorporation papers for the Health Insurance Plan of Greater New York (THE JOURNAL, May 13, p. 161), presented by Mayor Fiorello H. La Guardia, were filed August 31 with the state board of social welfare and the superintendent of insurance. If approved by these two agencies and by a justice of the state supreme court, the papers will establish a nonprofit membership corporation to pay insurance as the Health Insurance Plan of Greater New York. The papers will be filed with the secretary of state when the necessary approvals are obtained, and the plan will then be ready to function. The roster of incorporators includes many prominent names in medicine, it was stated, but does not include the names of representatives of five county medical societies. The United Medical Service, Inc., organized under the guidance of the medical profession and approved by the Medical Society of the State of New York, is circularizing physicians with a letter asking them to participate in this plan, which was also set up this year (THE JOURNAL, May 27, p. 296). In its letter to the physicians the United Medical Service reported that it would pay all bills on the basis of physicians' fees comparable with those in workmen's compensation schedules for subscribers whose incomes are "less than an amount to be determined by your board of directors and approved by the council of the Medical Society of the State of New York. When the subscribers' incomes exceed this amount, physicians will be privileged to make a further charge to their patients in addition to the fees which they will receive from the company." The mayor's tentative proposal has envisioned coverage "to every one who earns up to \$5,000 a year," it was stated.

OHIO

Dr. Markwith Ends Term as Health Commissioner.—Dr. Roll H. Markwith, Columbus, retired as director of the Ohio Department of Health on August 21, when his five year term expired, to become assistant medical director of the clinical laboratory owned and operated by Dr. Anson L. Brown, Columbus. Dr. Markwith had been health commissioner since January 1939, when a law enacted by the legislature in that year, reorganizing the state department of health and providing for a five year term for the director, became effective. In August 1939 Dr. Markwith was reappointed. Before becoming state health commissioner he had been health officer of Summit County. Until a new director is appointed by the governor, the department will be in charge of Mr.

James E. Bauman, LL.B., assistant director and chief of the legal division. In Ohio the law requires the governor to appoint a director of health from a list of five nominees submitted by the Ohio Public Health Council.

VIRGINIA

Dr. Porterfield Named Health Officer of Richmond.—Dr. Jack B. Porterfield has resigned as director of the bureau of industrial hygiene of the Virginia Department of Health, Richmond, to become director of the Richmond city health department, effective September 16. Dr. Porterfield graduated at University of Virginia Department of Medicine, Charlottesville, in 1933 and has been with the state department of health since 1939.

State Medical Meeting.—The ninety-sixth annual meeting of the Medical Society of Virginia will be held at the John Marshall Hotel, Richmond, October 23-25, under the presidency of Dr. Claude B. Bowyer, Stonega. Included among the speakers will be:

Drs. Frank S. Johns and James B. Stone, Richmond, Congenital Pyloric Stenosis with Series of Cases.

Dr. James Q. Gant Jr., Bethesda, Md., Dermatitis in the Munitions Industry.

Dr. Paul Hogg, Newport News, Erythroblastosis and the Rh Factor.
Dr. Alex F. Hartmann, St. Louis, Further Clinical Studies in Disturbances of Acid Base Balance.

Drs. Chas. H. Dawson, Suffolk, and Hubert D. Crow, Courtland, Report of Five Cases of Meningitis Treated Empirically with Sulfanilamide Under Rural and Low Economic Conditions.

Drs. Hugh P. Newbill and Randolph Leigh Jr., Richmond, Nonsurgical Therapy of Epilepsy.

Dr. Frederick E. Hamlin, Roanoke, An Investigation of Allergy in Routine Nose and Throat Practice.

Drs. George Cooper Jr. and Vincent W. Archer, University, Radiation and Neurosurgery in Advanced Pain.

Dr. Herbert C. Its Use in the

Dr. Wallace E. Penicillin.

Dr. Paul D. C. Heart Disease.

On Tuesday, October 24, clinics will be conducted under the auspices of the Medical College of Virginia. On Wednesday the Virginia Society of Chest Physicians will hold a luncheon meeting at Pine Camp. Various specialty societies plan luncheon sessions. The Woman's Auxiliary to the Medical Society of Virginia will hold its twenty-second annual meeting in Richmond at the John Marshall Hotel, October 23-24.

Special Examining Board in Basic Science Created.—Members of a three man special board of examiners in basic science, created by the 1944 general assembly to conduct examinations of applicants for licenses to practice the healing arts in Virginia, are Dr. Frank L. Apperly, professor of pathology, Medical College of Virginia, Richmond; Carl C. Speidel, Sc.D., professor of anatomy, University of Virginia Department of Medicine, Charlottesville, and Lucius J. Desha, Ph.D., professor of chemistry, Washington and Lee University, Lexington. The appointments were made by Governor Darden, according to the Richmond Times-Dispatch. The tenure of the board is five years. It was set up by the general assembly in the amendment to the healing arts statutes to permit the licensing of chiropractors and naturopaths in Virginia. The newspaper report stated that the purpose of the special board was to meet the objections that the state medical examining board, as now constituted, should not pass on the qualifications of chiropractors and naturopaths. The act specifies that the members of the special board shall be members of faculties of the accredited colleges of the state and shall not be medical practitioners. Examinations by the board will be limited to the basic sciences and shall include only the subjects of anatomy, bacteriology, elementary chemistry, pathology and physiology. The examinations are to be given in November of each year during the five year tenure of the board, with the first planned for November of this year. Under the act creating it the board may give examinations to all applicants for licenses to practice chiropractic or naturopathy who elect to take the special tests in basic science in preference to the more detailed examination in these subjects which is provided under the state board of medical examiners for applicants for licenses to practice medicine. A special provision in the act preserves the right of applicants in the military or naval service who, although otherwise eligible to take the special examinations, are prevented from doing so because of their absence from the state. Except for this exemption the special examinations are available only to those practitioners of chiropractic and naturopathy who were engaged in such practice for a period of one year prior to the effective date of the act, which was July 1. Applicants not in the armed services are required

to apply for the special examination prior to November 1 and to supply the board with satisfactory evidence of eligibility. The exempted servicemen may certify their eligibility at any time within six months after their discharge from the service.

WASHINGTON

Arthur Anderson Dies.—Mr. Arthur Anderson, executive secretary of the Washington State Medical Association for the past five years, died August 7 of coronary thrombosis, aged 47.

Stith Memorial Library.—The Dr. Robert M. Stith Memorial Association has been incorporated for the purpose of establishing a memorial library at Firland Sanatorium, Seattle. The nucleus will be the personal medical library of the late Dr. Stith, who was medical director of the sanatorium during the greater period of its existence, according to *Northwest Medicine*.

WEST VIRGINIA

Changes in Health Officers.—Dr. Ward L. Oliver, Point Pleasant, health officer for district number 3, has been transferred to Morgantown as health officer of Monongalia County. He succeeds Dr. William B. Bailey, who has been transferred to Norfolk, Va.

Dr. Angstadt Named Acting Director of Maternal and Child Hygiene Division.—Dr. Norman G. Angstadt, director of the bureau of county health work of the state department of health, has been appointed acting director of the division of maternal and child hygiene since the recent resignation of Dr. Lenore V. L. Patrick-Chipman (*THE JOURNAL*, June 24, p. 589).

Health Conference.—On October 16 the annual Northern District Health Conference will be held at the new West Virginia Training Center, Morgantown. Dr. James A. Dolce, Fairmont, director of the Marion County Health Department, will deliver the principal address, on "Public Health in the Schools." A feature of the conference will be the dedication of the training center.

New Clinics to Discover Cancer.—On August 31 Drs. Paul R. Gerhardt, director of the state division of cancer control, and J. Ross Hunter, Charleston, chairman of the cancer committee of the state medical association, conducted "case finding clinics" at Madison and Whitesville. The Boone County Medical Society cooperated in the clinics, arrangements for which were made by Dr. Robert L. Hunter, county health officer; nursing service was provided by the public health service and the Boone-Raleigh Clinic. Of 11 patients examined, 4 were found to have cancer. The clinics were conducted as an experiment. Regular tumor clinics have been established at the Laird Memorial Hospital, Montgomery; Mountain State Memorial Hospital, Charleston; St. Mary's Hospital, Huntington; Bluefield Sanitarium, Bluefield, and St. Mary's Hospital, Clarksburg. A tumor diagnostic clinic is now being organized in Morgantown under the auspices of the Monongalia County Medical Society, and the local medical societies are considering the establishment of similar clinics in Parkersburg and Fairmont. On September 15 64 active cases of cancer were under the care of the recently organized division of cancer control. Provision has been made for handling additional referrals without delay while applications for care through the new division are filed with the local departments of public assistance, and persons need not be receiving aid from this department to be eligible for cancer care. The department of public assistance furnishes information concerning the financial circumstances of the applicant, and the division determines whether the aid should be given. The possibility of developing additional channels through which applications may be made is now being given consideration with a view to speeding up the work of the division.

GENERAL

Call to Hunter College Graduates.—All women physicians who are graduates of Hunter College, New York, are asked to communicate with Ruth Lewinson, 18 East 41st Street, New York 17, president of the Associate Alumnae of Hunter College. The college is making preparations to observe its seventy-fifth anniversary and wishes to reach as many of its graduates as possible.

Funds for Infantile Paralysis During Epidemic.—The National Foundation for Infantile Paralysis on September 3 announced that, up to September 1, \$397,639 had been sent to twelve states to assist in defraying expenses incidental to the

prevailing epidemic of poliomyelitis. Of the total, North Carolina has received \$230,974. A total of \$51,311 has been sent to aid foundation chapters in New York State whose funds have been depleted in aiding victims, and another \$50,000 has been sent for a similar purpose to Kentucky. Other states which have received financial aid are Virginia, Ohio, Florida, Illinois, Iowa, Kansas, Mississippi, California and Oregon. In other states 50 per cent of funds retained by the foundation's chapters from the March of Dimes has been sufficient to provide proper medical care for all victims regardless of age, race, creed or color. Specially trained physicians were sent into North Carolina, Kentucky and New York, and thirty-five physical therapists were dispatched to fill the needs in fourteen states. A total of 6 tons of wool for hot packs has been shipped into thirteen states and the District of Columbia.

Association of Medical Colleges.—The fifty-fifth annual meeting of the Association of American Medical Colleges will be held at the Hotel Statler, Detroit, October 23-25, under the presidency of Dr. Ewen M. MacEwen, Iowa City. Among the speakers will be:

Drs. George S. Eadie and Wilburt C. Davison, Durham, N. C., Post-war Medical Education.
Dr. C. Sidney Burwell, Boston, Graduate Medical Education in the Postwar Period.
Drs. Donald B. Tresidder, Stanford University, and Winston-Salem, N. C., J. Gardiner, Chicago, Deceleration of the
Dr. Gordon B. Myers, Detroit, The Te
Drs. Loren R. Chandler, San Francisco
Charles D. Creevy, Minneapolis, Requirement of Internship for Graduation.
Drs. Joseph Turner, New York, and Leverett S. Woodworth, Detroit, The Internship: When to Contact Students; Time of Appointment.
Dr. Daniel E. Hasley, Detroit, The Teaching of Parasitology and Tropical Medicine.
Dr. William Dock, New York, Mixed Task Forces in Medical Education.
Drs. James A. Greene, Houston, George T. Harrell Jr. and Herbert M. Vann, Winston-Salem, Integration of the Curriculum: Overdepartmentalization.
Charles I. Reed, Ph.D., Chicago, A Study and Analysis of Faculty and Student Opinions of Training in Preparation for the Study of Medicine.

Young Mothers and Rapid Wartime Increase in Birth Rate.—Young mothers between the ages of 20 and 30 having their first child were the principal contributors to the rapid wartime rise in the American birth rate, according to the statisticians of the Metropolitan Life Insurance Company. The chief factor in the rise at the younger ages has undoubtedly been the recent upswing in the marriage rate. A good part of the increase, however, is accounted for by women who had been married for some time but delayed having children until economic conditions became more favorable. Although the general birth rate has increased with unequaled rapidity during the war period, the trend toward small American families as well is still in evidence. Families with five or more children have continued their long term prewar downward trend. Similarly the general trends of reproductivity in relation to the age of the mother have continued essentially along the lines prevailing just prior to the beginning of the war but in more accentuated form, it was stated. It was pointed out that from 1933, when the birth rate in this country reached its lowest point, to 1939, the increase in births was almost entirely concentrated among women under 30. Likewise between 1939 and 1942 white women at ages 20 to 24 "recorded the largest increase in the birth rate, 29 per cent; at ages 25 to 29 the rise was 26 per cent." The rate among women in their early thirties increased by 17 per cent during the war years since 1939, but in the group at the age of 40 or over the birth rate decreased between 1939 and 1942. First births showed a considerably larger wartime increase than any of the later orders of birth. The largest rise occurred among women in their twenties, among whom it amounted to 40 per cent; among women in their thirties the gain was 33 per cent. Families having their second or third child also showed considerable gains during the war period, while the data also indicate a small increase between 1939 and 1942 in the birth rate of fourth children. For children of fifth and higher orders of birth the long term prewar downward trend has persisted, giving every indication that the tendency toward small American families will continue, it was stated.

International Medical Assembly.—The Inter-State Postgraduate Medical Association of North America will hold its twenty-ninth annual International Medical Assembly at the Palmer House, Chicago, October 17-20. Among the speakers will be:

Dr. Bert I. Beverly, Chicago, Spoiled Children.
Dr. James L. Poppen, Boston, Intracranial Aneurysms: Diagnosis and Management.
Dr. Frank H. Krusen, Rochester, Minn., The Abuse of Rest as a Therapeutic Agent.
Dr. W. James Gardner, Cleveland Heights, Ohio, Subdural Hematoma.
Dr. Charles G. Johnston, Detroit, Intestinal Obstruction.

Dr. Harry L. Alexander, St. Louis, Primary Atypical Pneumonia.
Dr. Elliott P. Joslin, Boston, Diabetes Today.
Dr. J. Arnold Barger, Rochester, Management of Ulcerative Colitis.
Major Gen. David N. W. Grant, the Air Surgeon, Five Wartime Achievements of the Army Air Forces Medical Services.
Dr. Karl A. Menninger, Topeka, Kan., Diagnosis and Treatment of Schizophrenia.
Dr. Frederick A. Davis, Madison, Wis., What the General Practitioner Should Know About Ophthalmoscopic Examinations (the Schneider Foundation eye presentation).
Lieut. Col. Donald McEachern, R. C. A. M. C., Diagnosis and Treatment of Epilepsy.
Dr. Edward J. Stieglitz, Washington, D. C., Geriatrics in Wartime.
Dr. Donald C. Balfour, Rochester, Diagnosis and Treatment of Duodenal Ulcer.
Dr. Julian Deryl Hart, Durham, N. C., Air Borne Infections in Clean Operative Wounds.
Dr. Robert S. Berghoff, Chicago, The Senile Heart.
Brig. Gen. Fred W. Rankin, M. C., Comments on Surgical Methods Used in World War II.
Dr. Edward Weiss, Philadelphia, Psychosomatic Aspects of Problem Cases in the Practice of Medicine.
Dr. Richard B. Cattell, Boston, Colectomy for Ulcerative Colitis.
Col. Byrl R. Kirklin, M. C., Some Common Errors in X-Ray Interpretation.
Dr. Arthur Steindler, Iowa City, Disabilities Resulting from Compression Fractures of the Spine.
Dr. John W. Harris, Madison, The Use and Abuse of Forceps.
Norman T. Kirk, Surgeon General of the Army, Surgical Care of the Battle Casualty.
Dr. Oscar T. Clagett, Rochester, Surgical Treatment of Bronchiectasis.
Dr. Arlie R. Barnes, Rochester, Diagnosis and Treatment of Coronary Sclerosis.
Dr. Frank S. Dolley, Los Angeles, Chest Injuries.

In addition to these presentations, a number of diagnostic clinics will be conducted. At the assembly dinner Dr. Josiah J. Moore, Chicago, Treasurer of the American Medical Association, will, as general chairman of the assembly, give the welcoming address and introduce General Rankin, president of the association, who will speak on "Medical Activities in the Normandy Beachhead Landing." Other speakers will include Dr. Walter H. Judd, congressman from Minnesota, on "Our Prospects for the War and the Peace."

LATIN AMERICA

Health Activities in Latin America.—Traveling Health Requirements in Canal Zone.—On September 14 the Panama Canal Health Department issued a statement outlining vaccination and health requirements for traveling in the Canal Zone, emphasizing the need of a smallpox vaccination and freedom from contagious diseases. The quarantine division requires that every one coming into the Canal Zone present a certificate showing that successful vaccination has been performed within the preceding five years. If one does not have a certificate he must be vaccinated by a quarantine physician before he is allowed to enter the zone. The U. S. Foreign Quarantine requires that every person entering the United States must present a smallpox vaccination certificate. If a traveler does not possess one, quarantine officials insist that he be vaccinated before he is permitted to enter the United States. Because most Central and South American countries require smallpox vaccination certificates of incoming travelers, the consuls of these countries will not issue visas permitting entry unless shown a certificate. In 1940 the health department carried out a zonewide smallpox vaccination campaign. Copies of certificates based on this campaign may be obtained from the chief health officer. Record of preemployment vaccination is included in the personnel files of many Canal Zone employees who have come to the Zone during the past two years. Copies based on these records may be obtained from the chief health officer, as may copies based on records sent in the past to the chief health officer from the outpatient clinics of Panama Canal hospitals. The school physician has on file the records of vaccinations he has done on school children, and the district physicians have the records of vaccinations done in their dispensaries. Copies may be obtained from either of these sources. Many Central and South American countries also require a statement signed by a recognized physician certifying that the incoming traveler has been examined and found free of contagious disease. Since these countries will turn back travelers unless they have this statement, the Canal Zone Quarantine will not let a person leave the Zone without such statement if he plans to visit in one of them. For direct travel to the United States or for return to the Zone from the states or from these countries, this statement is not necessary. Statements certifying health may be obtained from any district physician, from the medical clinic of any Panama Canal hospital or from the chief health officer. Each person for whom such a certificate is issued must appear personally before the physician who is to sign the certificate. No other vaccination or health requirements must be met in order for Panama Canal employees or their families to travel.

Typhoid-paratyphoid inoculations are recommended for every one, and especially for travel in Central or South America, but are not required. Typhus vaccination is recommended for travel in certain Central and South American countries but is not required. Should there be epidemics or great health risks in these countries in the future, further recommendations will be made by the chief health officer.

Personal.—Dr. Carlos Estevez, formerly director general of sanitation of Guatemala, has joined the Pan American Sanitary Bureau, with headquarters in Mexico, for the study of filariasis.

Penicillin in San Juan.—Twenty million units of penicillin has been given to the San Juan Health Department for use in its campaign against gonorrhea.

Government Services

Name Aides on Rehabilitation

Brig. Gen. Frank T. Hines, Veterans Administrator, Washington, D. C., announced September 3 the appointment of four educators. The names of the appointees are Robert G. Sproul, LL.D., president of the University of California, Berkeley; Rufus C. Harris, LL.D., president of Tulane University, New Orleans; Robert B. Stewart, LL.D., controller of Purdue University, West Lafayette, Ind., and Horace S. Ford, bursar of the Massachusetts Institute of Technology, Cambridge, Mass.

Dr. Doyle Appointed to Industrial Hygiene Division

Dr. Walter E. Doyle, in charge of the bureau of industrial hygiene, Kentucky State Department of Health, Louisville, has been appointed chief of the medical unit, industrial hygiene division, Bureau of State Services, U. S. Public Health Service. Dr. Doyle's appointment was effective October 1. He graduated at the University of Buffalo School of Medicine, N. Y., in 1921.

Funds for School and Child Care Allocated

Federal contributions amounting to \$713,707 to help twenty-three communities meet operating costs of school, child care and recreation facilities were announced September 12. Thirteen of the communities were given a total of \$554,337 to help maintain school facilities for the year ending June 1945. The Roane County Board of Education at Kingston, Tenn., was allotted \$219,131 and five communities in Oklahoma were awarded contributions totaling \$227,007, with Tulsa receiving \$171,868. Child care programs in Lackawanna and Kenmore, N. Y., near Buffalo, Ecorse, Mich., in the Detroit area, and Fort Belvoir, Virginia, were among the projects assisted.

Funds for Public Works

The President has approved sixty-two new Federal Works Agency projects for financial assistance to war impacted communities to provide hospital, school, recreation and child care facilities. Federal funds allotted total \$2,017,050. Fifteen of the projects are for war public works construction. Federal allotments totaling \$945,943 were made for this construction. The total cost of the work is estimated at \$1,242,349. The applicants are to furnish \$296,406. The remaining forty-seven projects represent federal contributions to help defray operation and maintenance costs of hospitals, both general and venereal disease control, public schools, facilities for the care of children of mothers employed in essential work, and recreation programs. The federal contributions for these service projects aggregate \$1,071,107. Baltimore was allowed \$30,850 to assist in the operation of venereal disease hospital facilities. An allotment of \$563,500 to the St. Monica's Hospital and Health Center at Phoenix, Ariz., was increased to \$648,500 to expand the project to include a 40 bed contagious disease ward together with a 130 bed hospital building, 30 beds to be reserved for venereal disease patients, and a 78 bed nurses' home.

CORRECTION

Error in Location.—The location of Dr. Bertalan Hoch, whose obituary was reported in THE JOURNAL, September 16, page 187, should have been New York and not Jersey City, N. J.

Trial of the Russian Serum for Rheumatism with Unsatisfactory Results

The Empire Rheumatism Council reports that tests with the scanty supply of the A C B serum of Professor Bogomoletz from Russia have not given favorable results. The best that can be said is "not proven." Nevertheless, in view of the high reputation of Soviet medical research, it is possible that, with a more detailed statement of the best methods of use and some lead as to the type of rheumatic disease to which the serum is best adapted, it may be found that the claim advanced can be substantiated. As soon as war conditions allow the Empire Rheumatism Council proposes either to invite a representative of Professor Bogomoletz to visit England or to send a research scientist to Russia to make further investigations.

Death of Sir Arthur Hurst

Sir Arthur Hurst, the great clinician, has died suddenly at the age of 65 from an attack of asthma, a disease from which he was a lifelong sufferer, and British medicine has lost a most original mind. Much of his work was performed despite a continuous state of asthma. At Guy's Hospital he would arrive at 2 o'clock and give himself an injection of epinephrine, break away from his ward round at 3 for another injection and finally have one at 4 before leaving for home, white and tired but indomitable. He was educated at Oxford, where he took a first in the final honors school of physiology. He then went to the medical school of Guy's Hospital, where he had a distinguished career. After qualifying he studied in Munich, Paris and America. At the early age of 27 he was appointed assistant physician to Guy's Hospital with charge of the neurologic department. As a physiologist he had studied at Harvard the work of Cannon on the use of the opaque meal to record the shape of the stomach in casts and he had seen something of the kind attempted on the human stomach in Germany. At Guy's he was a pioneer in the study of the movements of the alimentary canal and the mechanism of pain. He was the first to distinguish two types of constipation—colonic, in which passage through the colon is delayed and dyschezia (difficult defecation, a word coined for him). In dyschezia the feces reach the rectum in normal time but their evacuation is delayed by insufficient defecation. Neglect to respond to the call to defecation may end in loss of the conditioned reflex in which the rectum contracts and the anal sphincter relaxes. The rectum is found packed with feces at whatever hour it is examined. The patient takes aperients to produce fluid feces which require no effort for evacuation. This work is regarded as a noteworthy contribution to the understanding and treatment of constipation.

His thorough and extensive investigations made him the leading authority on diseases of the esophagus, stomach and intestine. He wrote on these subjects in the textbooks, where he combined knowledge of the latest views on physiology and pathology with minute and original clinical observation. His work on achalasia of the cardia, gastritis, peptic ulcer and ulcerative colitis marked a great advance. He lived to see his views on the medical treatment of gastric ulcer generally accepted. He was a trenchant critic of current errors and debunked many mythical maladies, such as "mucous colitis." He pointed out that the presence of mucus with solid feces was a normal event and that it was a gross error to regard it as evidence of disease. He denounced the "colon laundries" which have become popular in recent years in this country. The colonic douche was an unnatural irritant, and the mucus which

came away with the last 20 or 30 pints often administered was not the accumulation of months, as the patient was assured, but a protective reaction against the irritation of the douche. Other mythical maladies exposed by him were movable kidney, gas troptosis and abdominal adhesions. He pointed out that when appendectomy failed to cure chronic pain in the right iliac fossa a second error was made and adhesions were diagnosed. But the majority of abdominal adhesions were harmless. Another mythical malady was intestinal intoxication due to intestinal stasis.

It was characteristic of his work that it always seemed to touch fundamentals and have a message for the general man or the expert in quite another branch of medicine. Thus he not long ago held the rapt attention of the Section of Proctology of the Royal Society of Medicine when he discoursed on Functional Diseases of the Colon and Rectum. His teaching that the so-called pernicious vomiting of pregnancy is hysterical has been adopted by leading obstetricians (*THE JOURNAL*, May 20, p. 223). Though a kindly man, his zeal for what he conceived to be the truth sometimes made his criticisms at medical meetings devastating.

In spite of his frail health his literary output was large. Some of his numerous articles in medical journals were collected in a book entitled "Essays and Addresses on Digestion and Nervous Disorders." His book "Constipation and Allied Disorders" (second edition, 1919) was translated into French (1912). "Medical Diseases of the War" was published in 1918 and the third edition appeared in 1942. Other books were "The Constitutional Factor in Disease" (1927) and "Functional Disorders" (1920). With a surgeon, M. J. Stewart, he cooperated in writing "Gastric and Duodenal Ulcer" (1929). He enjoyed an international reputation, as was shown by his presidency of the International Society of Gastro-Enterology and an honorary membership in the American Medical Association, the American and Mexican Gastro-Enterological associations, the Belgian Gastro-Enterological and the French Gastro-Enterological Association. From 1927 to 1929 he was president of the Section of Medicine of the Royal Society of Medicine.

Research on Pneumoconiosis

Though it has long been known that dust was injurious to the miners' health, only in 1918, twenty-one years after the first workmen's compensation act was passed, was silicosis made a "scheduled" disease for compensation, and only in 1934 was the plan extended to include any operation underground in any coal mine. Not until 1943 was it officially recognized that miners, especially in certain parts of the Welsh coal field might contract disease of the lungs which was not due only to dust containing silica. In February of last year an act was passed to bring into the scope of workmen's compensation all cases of pneumoconiosis. The way for this legislation was prepared by six years of scientific investigation in the pits of South Wales by a special committee of the Medical Research Council. Its reports resulted in an order compelling the adoption in any mine in South Wales or Monmouthshire of a variety of measures to reduce exposure of the men to dust and the appointment by the minister of fuel and power of an advisory committee on the treatment and rehabilitation of Welsh miners suffering from pneumoconiosis.

Already measures are being taken to suppress harmful dusts at working places in mines but the committee considers that further attention is needed to the treatment of affected persons and their restoration to health. Present legislation is insufficient to enable the committee to advise the introduction of large scale measures, further research into the cause, progress and treatment of the disease is left to local authorities. Accordingly, the establishment of a research unit with accommodations for about 30 patients is recommended. The unit is to be linked, through a central authority, with the pro-

ceeding on other phases of the problem; it is planned to acquire more precise knowledge of the causes and diagnosis of the disease, to develop and apply better methods of suppressing dangerous dust and to resettle and retrain disabled miners to take up more suitable employment. The committee also recommends initial and periodic clinical and x-ray examination of miners. Correlation of the findings with the results of pathologic research into early changes in the lung condition, the progression of those changes and the part played by tuberculosis and other infections will also be studied.

Radical Reforms of Medical Education

In spite of the war, reforms which embrace every aspect of social security are being worked out. As the proposed National Health Service will depend largely on the work of physicians, the government appointed a committee to inquire into the organization of medical schools, particularly as to clinical teaching and organization for research. The result of an exhaustive inquiry is an elaborate report recommending many radical reforms: (1) financial assistance to medical students so that children of ability are not deterred from entering the medical profession; (2) coeducation and filling of all hospital appointments by open competition without any sex bar; (3) whole time professors of medicine, surgery and obstetrics and gynecology in every school; (4) more emphasis on measures that make and preserve a healthy nation; (5) in clinical instruction, more emphasis on fundamental principles rather than on imparting a mass of factual knowledge; (6) after a student has passed the final examination, a junior appointment in a recognized hospital for twelve months before admission to the medical register; (7) postgraduate study a regular feature of general practice.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Aug. 25, 1944.

Vital Statistics of Rio de Janeiro for the First Half of 1944

Provisional data of vital statistics for the city of Rio de Janeiro for the first half of the present year are now available. During this period (mostly summer and autumn in the Southern Hemisphere) the total number of deaths from all causes was 16,989, corresponding to the crude annual death rate of 17.63 per thousand, as the city population computed for July 1 was 1,927,000. From the mean annual death rate of 26.00 per thousand of population for the five year period 1899-1903 this rate has declined to 23.55 for 1909-1913, to 21.95 for 1919-1923 and finally to 16.73 for 1929-1933. During this whole period yellow fever, plague and smallpox have been eradicated and malaria substantially reduced under the leadership of Dr. Oswaldo Cruz and afterward of Dr. Carlos Chagas, thus ending the first phase of the public health work in the capital city of the country. Now a second phase has been opened, the main features of which should be the conquest of tuberculosis, syphilis, typhoid, dysentery, diphtheria and measles and the lowering of infant mortality, the latter mostly of a nutritional and digestive origin. The success of the whole campaign is still waiting for the use of the modern weapons of public health work, especially in adequate intensity and quantity, or with the indispensable continuity. The number of live births registered during the period was 2,865, corresponding to an annual birth rate of 22.69.

The leading cause of death was tuberculosis, with a total of 2,977 deaths in the six months, which would correspond to an annual death rate of 309 per hundred thousand of population (325 in 1943, 312 in 1942 and 316 in 1941). The rest of the "infectious and parasitic diseases" has caused 2,096 deaths in the period, which, together with those from tuberculosis, makes a total of 5,073 deaths (29.86 per cent of the

deaths from all causes), or an annual death rate of 527 per hundred thousand of population as against about 95 per hundred thousand for the aggregate of the largest cities of the United States.

Cancer, which has caused 709 deaths, or 73.59 per hundred thousand (72.06 in 1943, 67.34 in 1942 and 66.44 in 1941) has been on a continuous increase as a cause of death since 1903-1907, when the mean annual death rate was 34.75. The second most important single group of causes of death is that of the diseases of the digestive system, represented by 2,690 deaths in the period covered, which would correspond to the annual death rate of 279 per hundred thousand. Diseases of the circulatory system accounted for 2,678 deaths, or the annual death rate of 278 per hundred thousand.

The diseases of the nervous system have caused 651 deaths, or the annual death rate of 67.57 per hundred thousand (65.40 in 1943, 65.94 in 1942 and 71.17 in 1941), the largest contribution being from "intracranial lesions of vascular origin," 461 deaths, or the annual death rate of 47.85 per hundred thousand. Violent deaths were 562, which would correspond to 58.33 per hundred thousand (56.67 in 1943, 65.51 in 1942 and 66.46 in 1941).

Retirement of Professor Austregesilo

Dr. Antonio Austregesilo, one of the leading figures of modern medicine in Brazil, has reached the retirement age after thirty-five years of active duty as professor at the University of Rio de Janeiro. He was the brightest pupil in the school of psychiatrists founded in Brazil by Dr. Juliano Moreira. Beginning as a psychiatrist in a small ward at the modest Praia Vermelha Hospital for the Insane, Dr. Austregesilo shifted little by little to neurology, which was then nonexistent in Brazil and which he established in the country as a new branch of clinical medicine. Thereafter he became a professor of neurology, teaching every morning in the famous twentieth ward of the old Santa Casa Hospital, where this specialty was taught in connection with the university. He made several trips to Europe, where he met the leading neurologists of London, Paris, Berlin and Vienna, as well as to Buenos Aires, where he was rated as the greatest neurologist of Latin America. In recent years the teaching of Professor Austregesilo was centered at the Institute of Neurology, a department of the old Psychiatric Hospital of Praia Vermelha. He has written many papers and monographs and several books, all dealing with neurology, and among his pupils are Mauricio Franca, Espozel, Teixeira Mendes, Studart, Galotti, Deolindo Couto, Aloysio Marques and Borges Fortes.

Brief Items

Two wards of the Gaffréc-Guinle Foundation Hospital of Rio de Janeiro have recently been set aside for the rapid treatment of syphilis. This is the first hospital service fully equipped in Brazil for this kind of work, and the foundation has decided to develop the service as the need requires.

The Sanitation Division of the Health Department of the state of Rio Grande do Sul has completed an extensive plan to provide water supply services and sewerage systems for several small cities of the state. An important sum has been appropriated to enable the state administration to cooperate with those small cities in the execution of the plan.

Marriages

JOHN SINCLAIR CAMPBELL, Manistee, Mich., to Miss Martha Anderton of Birmingham, Ala., in Evanston, Ill., August 12.

BEN THOMAS GALBRAITH, Henderson, Tenn., to Miss Mai Catherine Herron of Trenton, August 15.

ROBERT B. COFIELD, Cincinnati, to Miss Clara Hofferberth of Dayton, Ohio, recently.

Deaths

Frederick Clark Holden * New York; University of the City of New York Medical Department, New York, 1892; professor emeritus of obstetrics and gynecology at the New York University College of Medicine; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member and past president of the American Gynecological Society; member of the American Society for the Control of Cancer; fellow of the American College of Surgeons; obstetrician and gynecologist, French Hospital; consulting gynecologist, Harlem Hospital and the Bronx Maternity and Woman's Hospital; director of gynecology, Jersey City Medical Center, Jersey City, N. J.; consulting obstetrician, Methodist Hospital, Brooklyn, Mount Vernon Hospital, Mount Vernon, N. Y., and the Margaret Hague Maternity Hospital, Jersey City, N. J.; consulting obstetrician and gynecologist at the Bellevue Hospital, where he had been director of the gynecologic service for many years; in 1941 received the doctorate of public health from New York University; died in Prouts Neck, Maine, August 27, aged 75, of acute pulmonary edema.

Eben Homer Ben-net * Lubec, Maine; Jefferson Medical College of Philadelphia, 1875; an Affiliate Fellow of and in 1912-1913 delegate to the American Medical Association; past president of the Maine Medical Association and the Washington County Medical Society; acting assistant surgeon in the U. S. Public Health Service; school superintendent for fifty years; in 1894 one of the first public high schools to be established in Maine was opened in Lubec largely through his interest in public education; for many years physician to the Roosevelt family when it summered in Campobello, officiating at the birth of Franklin Jr. in 1914 and assisting with Franklin Sr. when he first became ill with poliomyelitis; in 1935, at the suggestion of Mrs. Roosevelt, awarded the golden emblem of the Beacon Circle of Honor, an honor paid by the Beacon School, Boston, to an individual "who is an outstanding example for youth"; in 1937 received the annual award of the Maine Medical Association for "outstanding service as a doctor"; died August 31, aged 96, of cerebral thrombosis.

Edwin Manson Neher * Laguna Beach, Calif.; Rush Medical College, Chicago, 1906; member of the House of Delegates of the American Medical Association in 1922, 1924,

1926 and 1928; member, past president and vice president of the Utah State Medical Association; member and past president of the Western Ophthalmological Society; member of the American Academy of Ophthalmology and Otolaryngology, Pacific Coast Oto-Ophthalmological Society and the American Ophthalmological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology; formerly ophthalmologist on the staff of St. Mark's Hospital, Salt Lake City, where he was also ophthalmologist for the Utah Fuel Company; died July 8, aged 69, of cerebral hemorrhage.

Thomas Harris Cherry * New York; Columbia University College of Physicians and Surgeons, New York, 1904; specialist certified by the American Board of Obstetrics and Gynecology, Inc., clinical professor of gynecology at the New York Post-Graduate Medical School, Columbia University; fellow of the American College of Surgeons and the New York Academy of Medicine; attending gynecologist at the New York Post-Graduate Hospital; consulting gynecologist, Suffolk County Sanatorium, Holtsville, Flushing Hospital and Dispensary, Flushing, and the All Souls Hospital, Morristown, N. J.; author of "Surgical and Medical Gynecologic Technic"; died in the Manhattan General Hospital August 30, aged 64, of coronary thrombosis.

Katherine Pritchard Hoyt, Wenham, Mass.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1887; died June 1, aged 79, of coronary thrombosis.

Charles Calvin Hubbard, Farmer, N. C.; Jefferson Medical College of Philadelphia, 1888; honorary member of the Medical Society of the State of North Carolina; member of the Randolph County Board of Health; died July 20, aged 76, of angina pectoris.

William Merritt Jones, Greensboro, N. C.; University of Maryland School of Medicine, Baltimore,

1903; honorary member of the Medical Society of the State of North Carolina; formerly a member of the state board of medical examiners; served as health officer of Guilford County; examining physician for the county draft board during World War I and II; medical director of the Jefferson Standard Life Insurance Company; died July 29, aged 63, of carcinoma of the lung.

"GILJAN" TESTIMONIAL OUTLIVES WRITER

"Wonderful Medicine" Fails to Save Him

On one page of the Cleveland News for July 20, 1944 appeared the testimonial of Alexander Kellough for "Giljan," reproduced here (reduced), and his death notice.

In his testimonial Mr. Kellough said, in part, "Giljan is a wonderful medicine. Any person having trouble such as mine

BACKACHE TORTURED HIM; WEAK FROM LOSS OF SLEEP

Mr. Alexander Kellough of 2508 F. Morris Block Place, Cleveland, Was Also in Misery From Indigestion, Gas Pains—Recommends Giljan as "Wonderful Medicine."

Mr. Alexander Kellough

Mr. Kellough's statement should bring comfort to thousands of suffering men and women who have sought in vain for relief from the same torturing miseries which this plague of our time has brought to thousands of Clevelanders. His testimony explains the amazement even of druggists, at the wonderful relief which Giljan is giving to so many who have agonized for years from stomach, liver, kidney ailments, bodily aches and pains. Mr. Kellough says:

"Constipation Slowed Me Up"

"I had backache and back weakness so bad that often it was hard to get out of bed mornings. I lost much sleep. My stomach was sour, too, and gas pains were so terrible I didn't care to eat. Constipation slowed me up, too, and kept me miserable. I have now taken at least 3 bottles of Giljan and feel

greatly improved. Back pains have disappeared and I sleep and eat much better. Giljan is a wonderful medicine. Any person having trouble such as mine should lose no time in taking it."

Made From Nature's Herbs

Giljan is an advanced medical compound containing juices from 18 health-giving herbs, roots, and barks. It is taken before meals and mixes with the food in one's stomach, thus helping to eliminate the poisons that foster stomach troubles and to permit the kidneys and liver to function properly. It usually acts within 10 minutes to stop gas pains, sourness, bloating and belching. Users say it will not gripe or nauseate you like ordinary liver medicines. It tends to make your liver more active and to clear away the old bile from your system. At the same time, Giljan has relieve sluggish kidneys and backache, caused by poor elimination.

Giljan is recommended and sold by all Marshall Drug Stores. Write to health. Start today by buying a bottle of Giljan. One bottle will convince you. Get the famous "Giljan" and save the price of a bottle. The Giljan Medicine Company, Keith Bldg., Cincinnati, O.

MARSHALL DRUG STORES

Mr. Kellough's testimonial.

should lose no time in taking it." Perhaps Mr. Kellough did lose time; the results indicate that he might better have advised, "Any person having trouble such as mine should waste no time or money on Giljan."

What is Giljan, which Mr. Kellough praised so fulsomely? What is the remedy which allegedly cleared up his backache, constipation, sour stomach and gas pains but failed to save his life? According to the carton front reproduced (in reduction) on this page, it is a "laxative herbal compound," though at least three of the ingredients listed—sodium benzoate, glycerin and saccharin—are hardly to be classified as herbal. Some of the other components named are outmoded in modern therapy, and altogether the combination of twenty declared substances recalls the old time "shot-gun" mixtures. Yet the carton declares it to be "compounded by Registered Pharmacists for Giljan Medicine Company, Cincinnati, Ohio."

That at least one government agency has objected to some of the Giljan publicity is seen in the complaint issued Sept. 16,

1944 by the Federal Trade Commission against the Giljan Medicine Company, Inc., its officers and their advertising agency on the charge that their newspaper and radio promotion contained false representations. Among these were that Giljan is a natural medicine and made from a new scientific formula, the ingredients of which substantially aid in giving health to the user; that the product is a cure for stomach trouble in its various forms, constipation, rheumatism, neuritis and liver and kidney ailments in general and also effective in relieving headaches and lack of energy; that it aids proper functioning of the kidneys and liver, clears old bile out of the system, strengthens the nerves, improves the appetite, relieves digestive disorders and has brought relief to 87 per cent of those who have used it. The complaint further charged that the preparation is an irritant laxative with no therapeutic value beyond that which a laxative offers, and that the advertisements are false for the further reason that they fail to reveal that Giljan is potentially dangerous when taken in the presence of abdominal pain, nausea or other symptoms of appendicitis.

Here a glance at the Giljan concern's antecedents is worth while, since they have some bearing on this latest endeavor of one Gilbert H. Mosby in the nostrum field. On May 26, 1942, according to official records,

he and two others incorporated the Mosby Medicine Company in Ohio, and on June 5, 1943 the name was changed to Giljan Medicine Company, Inc. The incorporators were reported as Gilbert H. Mosby, Samuel Stulberg and Benjamin S. Schwartz, the latter designated also as the statutory agent.

Mr. Kellough's death notice.

When the Mosby concern was incorporated, Mosby himself was said to be "broke" and to have been backed financially by Stulberg and a George B. Remus. It was further reported that Mosby called himself general manager of the company but refused to divulge the name of the president, who apparently turned out to be a Henry S. Dunlap. It appears that the "Giljan"

in the title "Giljan" was taken from Mosby's first name (Gilbert) and the "Jan" for Janice, said to have been the first name of one of his succession of wives. Further, it appears that Mosby was ousted by his partners some time in 1943 and died in June 1944 from the effects of a fall in the street.

But Mosby's record in the "patent medicine" field far antedated Giljan. Around 1927 he began to tell the world about the wonderful benefits to be gained by taking his "Konjola," advertised as the "surprising new medical preparation." It was claimed to contain no fewer than thirty-two ingredients, thus putting to shame the later Giljan, with its mere twenty, some of which were in Konjola. The advertising of Konjola abounded in testimonials, and one, published in the Meadville (Pa.) *Tribune-Republican* on Aug. 20, 1929 and enhanced by the Konjola concern's boast "Another victory for Konjola in a seemingly hopeless case after all the others failed," came from a man who had died three weeks before the testimonial appeared!

When Konjola had about run its course, Mosby appears to have shelved it for another nostrum, "Indo-Vin," which likewise was represented to be a mixture of thirty-two ingredients—perhaps the same thirty-two which comprised Konjola. Indo-Vin, however, seems to have been short lived, and ere long Mosby was introducing "Van-Tage," another "tonic." This time he was in the Far West and advertising "At Hollywood, capital of the motion picture world, Van-Tage is a sensation. This medicine is made there. The Immense Van-Tage Laboratories are located at Hollywood. So the stars of the screen are intimately acquainted with this Great Compound." These claims appeared in an advertisement which featured the testimonial of the stage and screen comedian Robert Woolsey. But within two years Woolsey died and his testimonial lost its kick. Another pan of praise for Van-Tage came from a Tom Nick and was featured in an advertisement in the Butte (Mont.) *Standard* Nov. 25, 1936, four days after another Butte paper had published an account of his funeral!

Thus the sordid procession passes in review—Konjola, Indo-Vin, Van-Tage, Giljan. Doubtless the sequence would have added a few new names had Mosby survived—and a few more death notices appearing with or prior to the corresponding testimonials. Funny, isn't it? But the reality is tragic!

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

Bel-Din.—This is a product of the Montrose Sales Company, Inc., trading as Montrose Products Company, Montrose, Calif. In January 1944 the concern and Guenther Bradford & Company, Chicago, an advertising agency, stipulated with the Federal Trade Commission to cease representing that the product will have any effect on the symptoms of asthma unless cardiac asthma is specifically excluded, or that it will relieve the symptoms of bronchial asthma beyond easing the difficulty in coughing and breathing. Also to be discontinued was any advertisement which did not reveal that the preparation is potentially harmful and should not be used by those having tuberculosis or goiter; provided, however, that such advertisement need contain only the statement, "Caution: Use Only as Directed" when the same warning appears in the labeling.

Benaris.—G. Bernardi of Cleveland, who puts out this product, stipulated with the Federal Trade Commission in January 1944 that he would discontinue any advertisement which did not clearly reveal that the too frequent or continued use of Benaris may cause nervousness, restlessness or sleeplessness; that its excessive use may cause injury to the lungs; that persons suffering from high blood pressure, heart disease, diabetes or thyroid trouble, or having a high fever should not use it except on the advice of a physician; also that without such advice the

product should not be used when hoarseness or a cough has persisted for ten days. The stipulation provided, however, that such advertisement need only contain the statement, "Caution: Use Only as Directed" if the labeling directions bear a similar warning.

Bondease.—That this product will stop ringworm and athlete's foot or relieve swollen feet, itching or burning skin or tired or sore feet (unless limited to such conditions when due to fungus infection) are misrepresentations which the Bond Pharmacy Company, Little Rock, Ark., which puts out the product, agreed to discontinue in a stipulation that it entered into with the Federal Trade Commission in February 1944.

Diopreen.—This preparation for "promotion of personal hygiene" is put out by Roycemore Toiletries, Inc., trading as Shy Products Company, Chicago. In December 1943 the concern stipulated with the Federal Trade Commission that it would cease representing that Diopreen contains 7 grains of oxyquinoline sulfate per tablet or that the amount of this or any other ingredient of the preparation is in excess of that actually contained therein; that oxyquinoline sulfate is recognized by or described in the United States Pharmacopeia, or that the company manufactures any preparation or article of merchandise unless it owns and operates or directly controls the plant in which the products it sells are made.

Godefroy's Larieuse Hair Coloring.—That this product "ends gray hair," "puts an end to dingy, off-color hair" or will correct "dull, gray-streaked hair" were claims which the Godefroy Manufacturing Company of St. Louis agreed to discontinue in a stipulation that it entered into with the Federal Trade Commission in January 1944. The stipulation recognized that such claims would tend to give the impression that the product will do more than dye the exposed hair to which it is applied, or that its use will cause the hair shaft, as it grows from the scalp, to be similar in color, type or condition to that part of the shaft to which the product has been applied.

Gotu Kola.—A stipulation regarding this was entered into in January 1944 with the Federal Trade Commission by George W. Moody of Pensacola, Fla. In this Moody agreed to cease representing that this herbal product has therapeutic properties in excess of what it actually possesses, or that the medical profession generally has knowledge of and uses or praises it; that it will increase the vitality of a person 70 or 80 years old to that of a 40-year-old individual; that it will bring about perpetual youth, exercise an energizing effect on the brain cells, revitalize worn-out bodies, prevent nervous breakdown or be an effective treatment for mental troubles, blood pressure, rheumatism, elephantiasis, bruises, fever, ulcers, leprosy, skin diseases, jaundice, neuritis or heart trouble, increase the span of human life or "pep up" the glands.

Granaya with Cascara.—This is a product of E. R. Squibb & Sons, New York, who in January 1944 stipulated with the Federal Trade Commission that they would discontinue any advertisement which did not reveal that the product should not be used when abdominal pain, nausea or other symptoms of appendicitis are present; provided, however, that the advertisement need only contain the statement, "Caution: Use Only as Directed" when the labeling instructions for use carry a warning to the same effect.

HQZ Hair and Scalp Oil, HQZ Shampoo, and HQZ Lustre.—These products were the subjects of a stipulation entered into with the Federal Trade Commission in January 1944 by HQZ Laboratories, Inc., and Rufus Rhoades and Robert Davis, trading as Rufus Rhoades & Company and Rhoades & Davis, advertising agency, all of San Francisco. In the stipulation the respondents agreed to cease representing that the Hair and Scalp Oil penetrates into the scalp pores or hair follicles, loosens dirt, grease and dandruff imbedded there, and opens clogged pores; that the Hair and Scalp Oil and the Shampoo, used singly or in combination, will rejuvenate the hair, bring to the surface any grease or other foreign substance lodged in the scalp pores, solve the dandruff or other "hair trouble" problems, prevent dandruff or falling hair, or impart any therapeutic benefit to the hair or scalp; that the presence of alcohol, alkaline soap or heavy oil in competitive products causes them to be harmful, or that HQZ Laboratories, Inc., owns, operates or controls a laboratory.

Laxtrate.—In March 1944 E. A. "Billy" Hamburg, trading as Vegetates Company, Los Angeles, stipulated with the Federal Trade Commission that he would discontinue any advertisements of this product which did not reveal that it should not be used when abdominal pains, nausea or other symptoms of appendicitis are present. The stipulation, however, permitted the statement in the advertisement, "Caution: Use Only as Directed," if the directions on the label should contain a warning to the same effect.

Milky Wayne Permanent Wave Solution.—This product is put out by Edwin K. Latz, Israel A. Latz and Sidney Seligman, trading as Seligman & Latz, New York City. A stipulation which they entered into with the Federal Trade Commission in January 1944 provided that they would cease representing that their product nourishes the hair and cannot injure it, and that the method of applying it is new or revolutionary. Further, they agreed to discontinue using the word "certified," which would give the impression that the product has been endorsed as to quality or fitness by any governmental, scientific or other recognized agency, or the words "Milky Wayne" or "milky bath" as part of the designation of the product, or representing through the use of picturizations or otherwise that the preparation is milk or contains milk.

Shasta Armenian Culture.—That this is nature's own balanced food, a life-prolonging item of diet, has destructive action on putrefactive bacteria in the intestinal tract and will rebuild the blood, nerves and glands were representations which S. Leila Hoover, Redwood City, Calif., agreed to discontinue in a stipulation that she entered into with the Federal Trade Commission in March 1944.

Correspondence

"MOBILE X-RAY UNITS IN INVASION"

To the Editor:—In THE JOURNAL, July 8, there appears on page 711, under the heading "Mobile X-Ray Units for Invasion," the following statement: "Hospitals in the field are unable to carry enough x-ray equipment to handle peak loads of patients. . . ."

I commanded an evacuation hospital in Italy throughout the Salerno-Cassino phase of the campaign. While in the combat zone, supporting the Fifth Army offensive closely, we had several peak loads of casualties during December 1943 and January 1944. On one occasion over 200 patients were admitted daily on three successive days.

Rain, gumbo mud, cold and litter carry in blackout were incidental problems encountered in this hospital, functioning entirely under tentage in the field. Thanks to the excellent prior planning, departmental organization and previous improvisation of equipment by Capt. Alfred A. J. Den, M. C., chief of the x-ray department, this department not alone kept abreast with the shock tents but was at all times one to one and a half hours ahead of the surgery for cases requiring operation.

At least one hospital in the field, therefore, was able to carry enough x-ray equipment to handle peak loads. It is not my purpose to belittle the work of Colonel Allen or the mobile x-ray units he has planned but to show that, by anticipating a possible situation and organizing to meet it, a hospital in the field can efficiently carry out its mission even during peak loads in the x-ray department.

JOHN W. McKOAN JR., Colonel, M. C., A. U. S.

DIRECTORY OF MEDICAL SPECIALISTS

To the Editor:—The biographic data of the first two editions of the Directory of Medical Specialists include only positions (internships, residencies or assistantships) held during the course of training of men up to the time of their certification by the American boards, and hospital and medical school staff positions then currently held.

It is desired to extend these data in the third edition to include all formal hospital and medical school appointments, with dates held, even though now resigned, as well as records of all military service including commissions and dates, either in World War I, peacetime in the Reserve forces or in the present war.

Thus a chronologically complete sketch of a certified specialist's entire career is to be included in this third edition of the directory.

Membership or fellowship in national or sectional (not local) special societies and national general societies with offices held, and dates in any of these, should be reported.

Membership in recognized international medical societies may be included, but honorary or other membership in foreign medical societies should not be reported.

Reference to the second edition (1942) of the directory may be made for lists of medical societies to be included in one's biographic sketch.

Families or secretaries of men absent in military service are asked to complete or correct previous listings or new forms now being mailed to those eligible for inclusion in the directory. Only those certified by an official American board can be included, and there is no charge for this listing.

Communications should be addressed to the Directory of Medical Specialists, 919 North Michigan Avenue, Chicago 11, Illinois.

PAUL TITUS, M.D.

Editor, Directory of Medical Specialists.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Gonorrheal Infection in Eyes Weakened by Industrial Injury Compensable.—In the course of his employment on April 30, 1942 some fluid used for a wood preservative splashed up into Graham's face and eyes. He was treated immediately at a first aid station maintained by his employer and again the next day by an "eye specialist," who discharged him May 3 as "being able to work." Two days later Graham returned to the physician and his right eye was found to be infected with gonorrheal germs. It is undisputed that Graham did not have any venereal disease and that the infection came from some source other than the workman. The infection spread to the left eye on May 8. As a result of the infection Graham eventually lost the sight of his left eye. He instituted proceedings under the workmen's compensation act of Arkansas and was awarded compensation by the workmen's compensation commission, which, among other things, found that

"It is recognized that gonorrheal infection, unless checked, will produce blindness" and "it is reasonable to assume that the infection found a ready portal of entry in the already inflamed and irritated eye of this claimant. In the opinion of the commission, the chain of causation has been established by this claimant, the liquid which was being used in his employment produced the irritation that offered a ready harbor for the gonorrheal infection that spread to the left eye and produced the blindness in the claimant's left eye."

The employer and his insurance carrier appealed to the circuit court, Phillips County, Ark., which affirmed the award of compensation. An appeal to the Supreme Court of Arkansas followed.

The employer and his insurance carrier contended that the award in favor of the workman should be reversed for two reasons: (1) It is speculation and conjecture for the commission to say that the irritated condition of the eyes, due to the industrial accident, made them more susceptible to the infection, and that blindness would not have occurred except for the irritation; and (2) even assuming the commission was justified in so finding, the germ infection was an intervening efficient cause, for which the employer would not be liable. With respect to the contention that it was speculation and conjecture for the commission to hold that except for the irritated condition of the eyes blindness would not have occurred, the court pointed out that while no witness testified that the irritation to the eyes made them more susceptible to gonorrheal infection it thought the commission had the right in the exercise of sound judgment and discretion to make the finding in this regard that it did make. It seems to us, said the court, a reasonable assumption that an inflamed and irritated eye, a conjunctivitis, would be a ready portal of entry for the germ that did attack the workman, or some other germ that he might have acquired. To support their contention that the germ infection which caused the blindness in the left eye was an intervening efficient cause which excused them from liability under the workmen's compensation act, the employer and his insurance carrier cited a number of cases, including *Bunge Bros. Coal Co. v. Industrial Commission*, 306 Ill. 582, 138 N. E. 189, to the effect "that an employee can only recover for a disability that is caused entirely by the accident which he received in his employment and that the employer is not responsible for any part of the disability that has been occasioned by another independent agency that has intervened after the accident occurred." In the *Bunge* case, said the court, the claimant was injured on March 8, 1920 in a

collision between a coal wagon he was driving and a street car. On the following July 15 his physician found him infected with acute gonorrhea of recent origin and on August 12 found the workman suffering with acute gonorrheal arthritis. In this connection the Illinois court said:

The proof is also to the effect that he (claimant) has suffered greatly from gonorrheal arthritis, and that the inflammation and swelling of the joints was occasioned by a new and independent cause, which occurred weeks after he received his injury.

So, continued the Supreme Court of Arkansas, it will be seen that the intervening efficient cause in the Illinois case occurred more than five months after the original compensable injury and had no connection with it. It was on these facts that the Supreme Court of Illinois used the language quoted. In a recent case decided by this court, *Garrison Furniture Co. v. Butler*, 177 S. W. 2d 738, Butler received superficial wounds on his hands while at work on April 16-17, 1942. On April 20 he consulted a physician and was sent to a hospital on April 21, where he died April 29 from lockjaw as a result of tetanus infection which entered the blood stream through the so-called superficial wounds. This court affirmed an award of compensation. It seems to have been assumed by counsel and the court in that case that if the tetanus bacilli gained entrance into the blood stream through the wounds on Butler's hands and caused his death and that if the wounds were received by him in the course of employment, compensation was properly awarded. The question there was: Did Butler receive his wounds to his hands from an accident injury arising out of and in the course of his employment? There was no question as to an intervening efficient cause. The injuries to Butler's hands were slight and superficial, but they formed a ready portal of entry for the tetanus bacilli, just as the inflamed and irritated eyes of Graham rendered them more susceptible to the entry of the gonorrheal germ.

The court, believing that the commission was justified in finding that there was a causal connection between the original injury and the resulting blindness in the left eye and that compensation was properly awarded, accordingly affirmed the judgment in favor of the workman.—*Pekin Wood Products Co. v. Graham*, 181 S. W. (2d) 811 (Ark., 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Concentrated Red Cell Transfusions M L Binder and A Klein—p 95

Amyotrophic Lateral Sclerosis—Wechsler and his associates studied 81 patients with amyotrophic lateral sclerosis personally observed between 1939 and 1942. Of this group they designate 68 as primary, the rest, although also fairly typical clinically, are regarded as symptomatic. They rigidly excluded cases of progressive spinal muscular atrophy and lateral sclerosis. They arrived at the conclusion that amyotrophic lateral sclerosis is not one disease entity dependent on one etiologic factor but a syndrome of varying etiology. The largest group consists of so called degenerative cases, some of which may possibly be the result of selective deficiency. Smaller groups may be the result of inflammatory processes or vascular changes. An even smaller group may possibly be toxic in nature. Amyotrophic lateral sclerosis, progressive muscular atrophy and uncomplicated lateral sclerosis are three different entities. The first is comparatively rapidly progressive and invariably fatal, the other two are chronic and last many years. While the intensity and extent of fibrillations often reflect the gravity of the disease, there is no constant parallelism between them and one cannot prognosticate on the basis of fibrillations alone. In many cases pseudobulbar manifestations may signalize the onset of amyotrophic lateral sclerosis. These studies confirm the want of parallelism between presence of active deep reflexes, absence of abdominal reflexes and a Babinski sign, despite involvement of the pyramidal tracts. The first always is present, the second two may or may not be.

Electrocardiographic Changes Following Artificial Hypertension—Clagett describes electrocardiographic studies in 86 patients who received 118 sessions of fever. Electrocardiograms were taken routinely on all patients before and after fever therapy. Tracings also were taken following conditioning fevers, since these offered an opportunity to study the effect of fevers differing in duration and intensity. Of 80 tracings taken following therapeutic fever, 64 showed insignificant changes, 7 showed significant changes and 9 showed no change whatever from the prefever tracing. The results of previous workers who claimed that the ST segment was almost always depressed following fever were not confirmed. It was found that there was a slight increase or decrease in the amplitude of the P waves and the QRS complexes and that the ST segment was depressed in a few cases. The most constant change

observed was an increase in the value of Bazett's K, an index of the duration of electrical systole. The authors discuss the effects of jaundice, acid-base balance and cardiac rate on the postfever electrocardiograms. Three cases with myocardial damage following fever therapy are presented. In 2 of the 3 almost complete recovery had apparently occurred when a relapse occurred in each, thirty-nine and fifty-six days respectively after fever. In cases of myocardial damage due to fever a good prognosis should not be given merely because the patient is young and the causative agent (fever) has been removed. The treatment of these cases should be the same as that given myocardial infarction due to any other cause. The authors also present 6 cases that showed transient and significant electrocardiographic changes following fever. They consider it highly probable that these transient changes were not on the basis of myocardial damage but rather due to temporary myocardial anoxia, possibly of a relative nature due to the tachycardia.

Concentrated Red Cell Transfusions—Concentrated red cell preparations used by Binder and Klein were obtained from regular hospital donors. The Fenwal apparatus, a semiclosed system, was used to collect 500 cc of blood in 50 cc of 5 per cent sodium citrate solution. The blood was typed by the open slide microscopic method and then stored at 4 to 6 C. The blood selected was from 2 to 7 days old. Before preparation the donor's blood was cross matched with that of the recipient. The plasma was aspirated off under sterile precautions into a pooling flask, the pipet was then inserted to the bottom of the bottle and the red cells were aspirated into a different bottle. The cells obtained from one donor blood in this way were called one donor unit of concentrated red cells. The concentrated red cells were either used immediately or returned to the refrigerator. The concentrated red cells were never kept longer than two days after preparation. They were administered in regular Upjohn recipient sets. The authors did not find it necessary to dilute the concentrated red cells in order to maintain the flow. The regular transfusion procedure was varied only by elevating the blood reservoir about 3 feet higher than usual to obtain a greater pressure. Thirty minutes was the average time required to administer each donor unit. Experience with 124 transfusions demonstrated that they are as efficacious as whole blood in raising the hemoglobin of anemic patients in whom only the cellular elements of the blood are deficient. The same amount of hemoglobin can be supplied in a smaller volume of transfused fluid. Concentrated red cells are of definite value in relieving anemia of patients with a reduced cardiac reserve, by reducing the chances of the production of cardiac failure and pulmonary edema. Theoretically it would also be of value to use concentrated red cells for patients who have recently bled and in whom there is danger of dislodging a newly formed clot by increasing too greatly the volume of circulating fluid with quantities of whole blood. Concentrated red cell transfusions have their limitations. They should not be used for acute blood loss until the blood volume has returned to normal and the only deficit is in hemoglobin. Their use is contraindicated in shock, burns and when the plasma proteins are below normal. The use of concentrated red cells is not limited to elevating the hemoglobin level. Evans reported that they are efficacious in controlling bleeding and other purpuric manifestations of blood dyscrasias. The authors have observed the same beneficial results in a case of monocytic leukemia.

Treatment of Acute Gonorrhea in Army.—Campbell and Carpenter state that in a ten month period 3,270 patients with acute gonorrhea were treated with sulfonamides at Fort Bragg, North Carolina. Following the institution of "duty status treatment" 1,170 cases were treated without hospitalization. The men on "duty status" continued their regular military duties and training while under treatment. Recovery of 79.1 per cent of the men occurred on a single five day course of sulfathiazole (20 Gm.) and an additional 12.5 per cent were rendered asymptomatic by a second similar course, giving a total recovery rate of 91.6 per cent. In the hospital treated cases there was a 10 per cent recurrence rate. "Duty status" treatment was highly successful and resulted in a great reduction of days lost from military duty and a large saving in hospital beds, as 93 per cent of these patients did not require hospitalization. No serious drug reaction was noted. Local treatment was infrequently used and, as a result, complications were rare. Larger doses of sulfonamides for hospitalized patients may effect a higher recovery rate.

One Day Treatment of Gonorrhea with Sulfathiazole.—Jacoby and Ollswang report observations on 69 men whose ages ranged from 17 to 27 years and in whom gonorrhea had existed from one to fourteen days prior to the institution of treatment. The treatment first tried was the administration of 2 Gm. of sulfathiazole four times a day; this was used for 2 patients. The first patient, through a misunderstanding, was given 4 Gm. four times a day. No ill effects were noted. The dosage was then modified so that 4 Gm. was administered twice a day; this was tried on 3 patients. As a further modification, the entire 8 Gm was administered at one time; this was used for 62 patients. Each patient was examined every day thereafter for one week. A urine specimen was examined twenty-four hours after medication. A complete blood count was done before and twenty-four hours after medication. Blood concentration of sulfathiazole was determined twenty-four hours after medication. There was relative freedom from serious toxic reaction. Five patients had minor toxic reaction. None showed anemia, leukopenia or disturbance in the number of granulocytes. Smears and cultures became negative in 35 cases in twenty-four hours, in 9 cases in two days, in 10 cases in three days and in 3 cases in four days. The discharge persisted in 25 patients after the smears and cultures became negative. Fifty-seven of these 69 patients were cured. Positive smears and cultures persisted in 12 patients. These were placed on a routine therapy of 4 Gm. of sulfathiazole daily for five days. Four of these patients were cured, 5 others remained persistently positive, 1 was doubtful, and 1 failed to return.

Penicillin for Impetigo Contagiosa.—Robinson and Wallace devised moist penicillin inoculated gauze pads to be used topically. Johnson describes his modification in the treatment of 25 patients with common pyoderma. Twelve patients with impetigo contagiosa were clinically clear of infection as early as three days and not later than seven days after the use of the penicillin-containing pads was begun. Four of the patients were previously treated with sulfonamides without improvement. Results for 2 patients with syeosis vulgaris showed promise that this method may become a new means of treating a stubborn recalcitrant infection. Ecthyma, streptococcal lymphangitis, a streptococcal infection of an ear and an abdominal cutaneous wound healed within eleven days. An ulcer of the leg due to Staphylococcus aureus of three months' duration had healed 90 per cent in six weeks after all methods of local therapy had been used. Production of crude penicillin presents many difficulties. Contamination of the pure culture of Penicillium notatum could render it useless and possibly dangerous. Penicillin pads and liquor should be tested for their potency by a ring test before they are used. Topical penicillin therapy will possibly supplant use of sulfonamide compounds or be a valuable adjunct. Absence of local reaction and sensitivity places the mold in a unique situation in comparison with the

sulfonamide compounds. A possible pitfall in the local use of penicillin is the suggested theory that one may become penicillin fast by repeated small applications. This hypothesis can be proved only by time and experience.

Immunization Therapy of Warts.—Biberstein describes an immunization therapy for warts which consists of injections of an extract of the lesions. First results of its use were published in 1924; since then reports have been published repeatedly, including also reports of successful treatment of warts in cattle and horses. He rejects the theory that the results obtained in the treatment of warts were due to suggestion. Many of the methods used may have one important point in common: they act by way of the vegetative nervous system. Results accomplished with injections of an extract of warts and of condylomata acuminata are due to immunizing factors. While this treatment can be used in any case of warts, it is indicated particularly in the presence of an excessive number of warts, in warts in locations in which other methods are impracticable or inadvisable (subungual region, nail wall and plantar region), in warts resistant to other methods of treatment and in recurrences following the administration of other treatments.

Dermatitis Due to Nail Polish.—Keil and Van Dyck report observations in 26 cases of nail polish dermatitis in which they were able to make patch tests with toluene sulfonamide resin and a number of related substances and derivatives. The data support Simon's view that toluene sulfonamide formaldehyde resin is the chief cause of nail polish dermatitis as seen today. The occurrence of so many cases is moreover consistent with the relatively recent introduction of this synthetic resin. In 25 of the 26 subjects, tests with toluene sulfonamide formaldehyde resin, which is not a primary irritant in the concentration used, elicited intensely positive reactions. Hypersensitiveness to this resin is frequently accompanied by group reactions to related chemical fractions and derivatives, such as the condensate of toluene sulfonamide and formaldehyde, toluene sulfonamide and, to a lesser extent, formaldehyde. This principle of group reactions seems also to extend to sulfanilamide. In 1 of 4 subjects with nail polish dermatitis a definite positive reaction was elicited with sulfanilamide; the patient had never used this or related compounds either internally or externally. Toluene sulfonamide formaldehyde resin was established by patch tests as present in one of the straw hat lacquers found on the market. This resin appears not to be present in the hair lacquers which have lately caused instances of contact dermatitis. A person hypersensitive to toluene sulfonamide formaldehyde resin is usually unable to tolerate the majority of nail polishes commonly used. A negative reaction to a patch test with this resin does not eliminate nail polish dermatitis due to another cause.

Renal Damage Due to Sulfonamide Compounds.

Murphy and his co-workers report clinical and pathologic data for 14 patients in whom renal damage developed after therapy with sulfonamide compounds. Thirteen of the 14 patients died and were studied post mortem. Decapsulation of the kidney was done and a biopsy specimen taken of 1 patient who recovered. Most of the commonly used sulfonamide compounds were employed, but sulfathiazole was the most commonly used. The primary disease under treatment was considered to play no part or at any rate a small one in causing the renal damage. The quantity of the sulfonamide compound administered and the

drug level in the blood appeared to be unimportant in producing the renal damage. As much as 41 Gm. and as little as 10 grains (0.6 Gm.) were responsible for fatal renal injury. In a few of the cases deposits of crystals of the drugs in the urinary tract causing some degree of mechanical obstruction were found associated with the nephrotoxic lesion; but this was not the rule, as in most of the cases reported the nephrotoxic lesion was independent of mechanical blocking. Microscopically there was simple tubular degeneration present in all the kidneys regardless of what other changes were present. Advanced tubular degeneration, necrosis of the tubular cells and intense inflammatory reaction outside the nephron in the surrounding tissues occurred in some cases. These various tubular lesions undoubtedly represent degrees in the severity of one process rather than different kinds of response. In 1 case advanced changes in the glomeruli were noted.

Infectious Mononucleosis.—According to Contratto a young adult with symptoms of cold, sore throat and grip should be suspected of having infectious mononucleosis and the necessary laboratory tests should be made. The author and his associates attended a large number of young men suffering from this disease. From 1935 to 1943 there were 12,601 men admitted to the Stillman Infirmary, of whom 249 had a discharge diagnosis of infectious mononucleosis. Of this number 53 were eliminated as not presenting a typical enough picture. Type and severity of symptomatology varied greatly. Sore throat was the most common symptom. Although it did not occur as the presenting symptom in more than 50 per cent of the cases, it developed at some time during the course of the illness in all except 18 per cent. Headache often heralded the onset of the disease. Fatigue and general malaise were frequent. Gastrointestinal symptoms were not prevalent, but anorexia was common. A presenting symptom of stiff or sore neck was usually referable to the swollen cervical lymph nodes. The onset of the lymphadenopathy was usually found in this area and often on the left side. The symptoms of ordinary infections of the upper respiratory tract with nasal congestion, fever and chills were conspicuous. The spleen was palpable in 91 cases. In several cases the spleen was definitely tender. The diagnosis of infectious mononucleosis cannot be made unless either the heterophile reaction of Paul and Bunnell is positive in high dilution or the blood smear is typical. The author stresses the importance of making frequent tests and smears during the course of the illness, since there is often a delay of days or even weeks before the hematologic changes are conclusive enough to permit an accurate diagnosis.

Circulation in Traumatic Shock in Man.—Richards describes a technic for measuring in man both the pressure of blood in the right auricle and the total volume flow of blood or cardiac output. These measurements are achieved by means of a long ureteral catheter introduced into a median basilic vein and thence passed along axillary and subclavian veins into the right auricle. The technic was originated by Forsmann with himself as subject more than ten years before. The technic

has been perfected and has proved to be remarkably easy, safe and painless, no serious untoward effects having been encountered in over 250 catheterizations. The research was pursued jointly by three groups: A group under Courmand was responsible for measurements of pulmonary ventilation and respiratory gas exchange, arterial and venous blood gas analyses and the catheterization technic; a group under Gregersen provided blood volume determination by the use of the dye T-1824; a group under Smith provided optical registration of arterial pressure tracings by the use of the Hamilton manometer. In a number of cases renal clearance studies were made by Smith's technic. The clinical material consisted of injured patients admitted to the Bellevue Hospital emergency service. All instances of shock were of the secondary, progressive form. While different injuries led to circulatory failure in different ways, the essential finding in all appeared to be an inadequate venous return of blood to the heart with diminished cardiac output. A deficit in circulating blood volume was responsible. Observations on the vascular bed in shock are summarized as follows: 1. In shock with blood loss there is a tendency to selective vasoconstriction, which is compensatory. 2. This compensation may fail, either gradually or suddenly. The patient in shock is in an unstable state, and the smallest additional trauma or disturbance may have disastrous effects. 3. Elevation of the feet in shock usually raises arterial blood pressure and is beneficial. 4. Drug therapy of shock is not satisfactory at present, but certain drug effects may prove to be helpful for peripheral circulatory failure. 5. Alcohol causes vasodilatation, which is unfavorable. 6. The most effective treatment is replacement of blood volume. When whole blood has been lost in large amounts, replacement by plasma alone will produce an acute anemia. The preference for whole blood in treating these types of injury has been increasingly emphasized in military casualties in this war. Restoration of blood volume brings the patient out of acute circulatory failure but is not complete treatment in itself. There is need for increased amounts of sodium salts and proteins. Fluids, salts and food should be started by mouth in the post-shock state as soon as tolerated. Oxygen therapy is frequently a necessity in chest injury and might be helpful in many cases of burns. The central circulation is better maintained if the volume of blood in the extremities is minimal, and in this sense cool extremities, particularly the avoidance of external heat applied to them, should be beneficial. This does not mean that the body as a whole should be subjected to cold. Exposure to cold affects shock most unfavorably:

Antisulfonamide Action of Serum and Resistance to Sulfonamide Therapy.—Boroff and his collaborators demonstrated that serums of certain individuals have an antisulfonamide action when tested in vitro. Boroff attempted to correlate this action with the resistance to sulfonamide therapy by certain patients with gonorrheal urethritis. A group of 18 patients with gonorrheal urethritis was selected. Thirteen of them had chronic gonorrhea and had received three or more courses of either sulfadiazine or sulfathiazole or both without apparent effect. The other 5 were patients with acute gonorrheal urethritis who showed no resistance to the drug and who were completely cured by one or two courses of sulfathiazole. From each of the selected patients 25 cc. of blood was taken under sterile conditions, and the serums were studied for antisulfon-

amide action. The results indicate that there may be a relationship between the in vitro manifestation of antisulfonamide action of the serums and the resistance to sulfonamide therapy. The fact that this antisulfonamide action may be measured in the laboratory presents a possibility of predicting the magnitude of the dose of drug necessary for chemotherapy to be effective. The success of the therapy may thus be prognosticated. Potentially resistant cases, instead of being subjected to prolonged and ineffective drug therapy, may be immediately determined in the laboratory and some other form of therapy applied.

Urinary Secretion at High Altitudes.—According to Malmjac urinary secretion decreases at high altitudes and elimination of nitrogenous wastes is momentarily upset. A series of experiments with dogs was undertaken at the Medical Schools of the Universities of Marseille and Algiers and at the Laboratory of Medicophysiology Research of the French Air Force in Algiers to determine the causes which disturb urinary secretion at high altitudes. Studies were made on the effect of depression on urinary secretion, the role of the renal nervous system, the effects of the secretion of epinephrine, the influence of peripheral physical factors, eventually intervention of various chemical factors, the role of gas bubbles and the like. The observations revealed that barometric depression is followed by a progressive decrease in urinary secretion. This reduction begins to manifest itself at a depression corresponding to an altitude of 12,000 to 16,000 feet. Three major actions occur successively to produce the oliguresis: (a) Nervous action: This is the principal one and the first which can be observed. It brings on renal vasoconstriction, origin of the oliguresis which appears from 12,000 to 16,000 feet. (b) Humoral adrenal action: This appears after the nervous action, when the depression corresponds to an altitude of 24,000 feet. (c) Physical action: This is represented by gas bubbles, which are produced at great depressions corresponding to more than 30,000 feet. These three factors complement one another. They not only bring about a progressive reduction of the urinary secretion but also modify the composition of the urine. The oliguresis has as a corollary the diminution of chlorides, the elimination of which is greatly disturbed. The inhalation of oxygen prevents the effects of the nervous and humoral actions.

Action of Penicillin on Staphylococcus in Vitro.—In view of the usefulness of turbidimetric methods for the measurement of the rate of bacterial growth in the study of sulfonamide bacteriostasis, Rantz and Kirby decided that similar techniques might be applied in the determination of the mode of action of penicillin. They used these methods in studying the effects of penicillin on various strains of staphylococci. They found that penicillin is actively bactericidal for the staphylococcus and that lysis of the organism occurs in the course of its action. This has not been demonstrated for the hemolytic streptococcus. Whether this dissolution of the organism is the result of the direct action of penicillin on the cell membrane or is caused by autolytic enzymes present in the bacterial cell that become active as the result of interference with vital bacterial metabolic processes by penicillin cannot now be determined. The latter hypothesis is, perhaps, the more probable since it is known that

staphylococci will, under certain circumstances, undergo spontaneous lysis. In spite of the ease with which enormous numbers of staphylococci can be killed and lysed by small amounts of penicillin, many organisms remain alive even after prolonged exposure to this chemical. The remaining viable bacteria on retesting may be shown to be as sensitive to the action of penicillin as was the parent strain, so that their survival is not the result of artificially induced penicillin resistance. The presence in the blood and tissues of 0.1 to 0.2 unit of penicillin per cubic centimeter would, on the basis of the observations recorded in this report and those of Rammelkamp, in which staphylococci were exposed to the action of penicillin in whole blood and serum, seem to be adequate for the therapy of most clinical infections. It is generally stated that penicillin is not inhibited by serum, body fluids or peptones. The observations described here indicate that lysis occurs somewhat more slowly and that more organisms remain viable after prolonged exposure to penicillin if a rich broth is used rather than the relatively incomplete synthetic medium. When peptones were added to the synthetic medium in increasing concentration, the control organism multiplied more rapidly but penicillin activity was unimpaired. This is in striking contrast to the action of the sulfonamides. It is possible that the constituents of the culture medium have no effect on the inhibitory phase of penicillin action on the staphylococcus but are concerned in the ease with which the agent may induce lysis and killing of the bacteria. The authors conclude that penicillin is an extraordinarily potent agent which in minute amounts induces the death and lysis of staphylococci. That this effect is not complete and that viable organisms remain after prolonged exposure to the drug is unfortunate and may explain certain clinical failures. There is a close correlation between the concentration of penicillin and its activity. By the methods described in this report a great natural variation in the sensitivity of strains of coagulase positive staphylococci to the action of penicillin may be demonstrated the clinical significance of which has not been evaluated.

Vitamin Content of Variety Meats.—McIntire and his associates analyzed the thiamine, riboflavin and nicotinic acid content of samples of bologna, frankfurters, pork links, beef liver, veal heart, Canadian bacon, various types of sausage, head cheese, oxtail, lamb shank and other variety meats. They found that these meats are a good source of the aforementioned vitamins, containing about the same amounts as fresh muscle meats. Retention of these vitamins in some of the meats was studied during broiling, braising and boiling. Greater amounts of all the vitamins were retained in the meat after broiling than after braising. In the case of boiling the vitamin retention in the meat was dependent on the cooking time. Broiling favored a higher total retention of thiamine than did braising. In nearly every case over 90 per cent of the nicotinic acid and riboflavin was recovered in the meat and drippings.

Nutritional Value of Soybean, Peanut and Cottonseed Flours.—Jones and Divine studied the growth promoting values of the proteins of soybean, peanut and cottonseed flours by the rat growth method and also their values as supplements to the proteins of wheat flour. They found that soybean, peanut and cottonseed flours contain proteins of high nutritive value and offer an excellent means of supplying dietary protein to extend and partially replace protein foods of animal origin. These plant proteins are well adapted to enhance the nutritive value of the proteins of wheat flour. The addition of as little as 5 parts of peanut, soybean or cottonseed flour to 95 parts of wheat flour produced mixtures containing 16 to 19 per cent more protein than wheat flour alone and a protein combination that was definitely superior in its growth promoting value to the same quantity of protein from wheat flour.

Renal Aplasia.—Nation believes that the term renal aplasia should be reserved for incompletely or defectively developed kidneys to distinguish the condition from renal agenesis, in which no vestige of renal tissue is to be found. There are clinical and embryologic reasons for restricting the use of the

term still further. To distinguish renal aplasia from hypoplasia and secondary atrophy it has been used properly only to denote the presence of tissue of metanephric origin which has never developed renal function or has undergone congenital atrophy. Confusion can be avoided by use of the criteria established by Gutierrez: "No true kidney; no evidence of pelvis; absence of true renal pedicle; renal artery small or absent; ureter incompletely developed and not patent; no excretion of urine; no renal function; histologic section of the supposed renal mass reveals glomeruli and tubules, showing arrest of development of renal organ." All of the cases designated as renal agenesis, aplasia and hypoplasia among approximately 27,000 necropsies performed at the Los Angeles County General Hospital were studied. There were 16 cases of true renal aplasia. Its incidence in this series was about the same as that of renal agenesis. Renal aplasia usually results from failure of proper contact between the ureter (collecting tubule system) and the metanephros. Three cases were bilateral. The right and left kidneys were involved with equal frequency. Nine of the patients were males and 7 were females. Six of the 9 patients living more than one month died as a result of hypertension, each having extensive disease of the functioning kidney. Four patients, 3 females and 1 male, had developmental defects of the genital tract. A case of persistence of the metanephros without a ureter is reported. Renal aplasia can seldom be differentiated clinically with certainty from renal agenesis. Surgical exploration for and removal of an aplastic kidney are indicated (1) for the relief of pain, (2) in patients with intractable hypertension and no evidence of disease of the functioning kidney and (3) in cases of hypertension in which pyelonephritic contracture or renal hypoplasia cannot be excluded.

Thrombosis of Renal Vein.—Melick and Vitt describe a case of thrombosis of the renal vein in which blood prothrombin times were obtained preoperatively. A retrograde pyelogram was secured in a normal fashion within a short time after the onset of the thrombosis, which showed the early roentgenologic changes of renal vein thrombosis. They believe that this is the first time that such a pyelogram has been obtained. In the pyelogram which was made within eighteen hours of the onset, as judged by the pain and tenderness, the swelling had not completely occluded the renal pelvis. The picture showed a renal pelvis irregular in outline and irregularly filled. In adults, renal vein thrombosis may be due to primary hematogenous pyelonephritis, with resultant thrombosis within the renal cortex and later extension to the pedicle. It may also be due to the involvement of the pedicle by infection from rupture of a cortical abscess or a perinephric abscess. Thrombosis of the renal vein may be part of a progressive, ascending inflammatory process involving first the vessels of the pelvis or lower extremity and then the inferior vena cava and its higher branches. In infants the thrombosis is almost always secondary to severe ileocolitis or gastrointestinal upsets. One case in an infant was secondary to a primary pneumonitis. If the possibility of such thrombosis is kept in mind, the diagnosis should be made without difficulty. The onset is usually sudden; there are fever, pain and tenderness in the affected side. On palpation the kidney has been found to be enlarged in every case reported. The kidney is also freely movable and tender. Usually there are signs of infection and severe toxicity. Frank hematuria or microscopic hematuria has been present in almost every case. In infants a history of previous ileocolitis is obtained. In adults the history of a previous thrombophlebitis of the pelvis or lower extremity is a common finding. Immediate nephrectomy seems to be the treatment of choice. A possible aid in the treatment may be the use of an agent such as dicumarol to prolong the prothrombin time. This agent must be used with great caution.

Podophyllin Treatment of Condylomata Acuminata.—Culp and his associates used podophyllin in the treatment of 100 young men with condylomata acuminata in the genitourinary section of the station hospital of Camp Bowie, Texas. Three of the patients also had chancres and 1 had acute gonococic urethritis, which did not complicate or prolong the condylomata treatment. The remaining patients did not have venereal disease. All but 7 patients were treated as outpatients while on full field duty. The lesions were confined to the penis,

perineum and anal area. Twelve patients had been treated by other methods (6 with acid solution of mercuric nitrate, 6 with electrofulguration) without complete disappearance of the growths or with early recurrences. In 62 cases treatment consisted of topical applications of 25 per cent podophyllin in liquid petrolatum with a cotton swab. This is prepared by suspending the crude podophyllin in liquid petrolatum and shaking well before each administration. No discomfort was experienced during the application and no anesthesia was required. Only 6 patients required more than one treatment. Most patients were cured within two to three days. The condylomas quickly turned white and dropped off, leaving a smooth, non-ulcerated base with no gross scarring. Only 2 recurrences have been reported from this group. The two responded promptly to the same type of therapy. In 35 cases the podophyllin was applied in a paste prepared by mixing the crude powder with water until the desired consistency was obtained. The drug appears to be equally efficacious when employed in this form and may be kept more localized. Only 2 patients required more than one application of the paste. The surrounding normal tissue usually is unaffected by the drug, but in isolated cases of extensive application under a tight prepuce some balanitis may result. Occasionally circumcision will be advisable because of the chemical balanitis and secondary preputial edema, but disappearance of the condylomas simplifies the surgical procedure.

Myocardial Infarction Without Coronary Artery Disease.—Simmons and Wolfson report that a man aged 31 was hospitalized because of substernal pain which radiated to the left shoulder and down the inner aspect of the arm to the third and fourth fingers. He had been free of complaints up to the day of illness. Immediately after the noon meal he attempted to climb a sharply graded mountain approximately 1,600 feet in height. About one third of the way up he experienced some nausea and stopped to rest. After a brief period he continued

climbing but soon felt a substernal fullness as though 'gas was crowding his heart.' He rested a second time and proceeded to climb. About two thirds of the way up he experienced a substernal ache. He rested a third time and climbed more. A few minutes later the pain became severe and radiated to the left shoulder and down the inner aspect of the left arm to the third and fourth fingers. This time the pain persisted in spite of rest. The patient was taken by litter and ambulance to the hospital. During hospitalization he continued to have mild substernal distress and numbness and tingling of the left arm in decreasing intensity through the fourth day. The patient was at bed rest for three weeks, was then allowed up for a short interval at a time in a wheel chair and was gradually permitted restricted activity. Convalescence was uneventful. The problem of acute heart strain resulting in myocardial infarction in the absence of coronary artery disease is still a controversial subject. Parsonnet and Bernstein concluded that acute heart strain occurs in the healthy as well as the diseased heart, reasoning that the man who is working at full capacity, and who then adds a little more to this exertion, may suddenly find himself with an inadequate blood supply to a portion of his myocardium, with resultant changes identical in every respect to those seen after a coronary occlusion or thrombosis. The sequence and progress of events in the case here reported make such an occurrence likely. The authors consider it probable that other such cases will be observed with greater frequency as more men are inducted into the service and participate in physical exertion foreign to them in civilian life.

Diseases of Veins. J. Homans.—p. 51.

Treatment of Pemphigus.—In two recent communications Lever and Talbott reported that significant changes in the electrolyte content of the blood serum occur in patients with pemphigus vulgaris. In an attempt to correct the chemical changes, they have treated patients with pemphigus vulgaris with adrenal cortex extract, dihydrotestosterone or massive doses of vitamin D. In the two previous publications observations on 15 patients with pemphigus were reported; since then an additional 17 patients have been studied. The authors report chemical findings in the blood serum of these patients and evaluate the effectiveness of adrenal cortex extract, dihydrotestosterone and massive doses of vitamin D. They recognize six types: pemphigus vulgaris acutus (Brocq's pemphigus subaigu malin), pemphigus vegetans, pemphigus vulgaris chronicus, pemphigus foliaceus, pemphigus erythematosis (Senear-Usher type of pemphigus) and pemphigus conjunctivae. In pemphigus vulgaris acutus, pemphigus vegetans and pemphigus vulgaris chronicus the amount of sodium, chloride, calcium and protein in the blood serum was found to be reduced. These changes were more pronounced in pemphigus vulgaris acutus and pem-

phigus vegetans than in pemphigus vulgaris chronicus. The degree of reduction usually corresponded to the severity of the clinical condition and the amount of skin involved. No etiologic significance can be attached to the chemical changes. They are regarded as a secondary symptom produced by the disease. Thirty-two patients with pemphigus were treated with adrenal cortex extract, dihydrotachysterol or massive doses of vitamin D. Encouraging results were obtained in several cases of pemphigus vulgaris acutus, pemphigus vegetans and pemphigus vulgaris chronicus. The results of treatment in cases of pemphigus foliaceus, pemphigus erythematous and pemphigus conjunctivae were disappointing. The treatment tends to correct the reduction of sodium, chloride, calcium and protein encountered in such patients. Since it is believed that the chemical changes are secondary symptoms produced by the disease, the treatment is merely symptomatic.

Chronic Digestive Disturbance in Elderly Patient. D. D. Paulus.—p. 297.

Restoration of Breathing.—Drinker says that if artificial respiration is applied at the time at which breathing stops, chances of recovery are 100 per cent. From the second to the sixth minute the chances decrease abruptly, and from the sixth to the twelfth minute the chances of regaining breathing are possible but slight. Large numbers of people requiring instant application of artificial respiration are treated first by laymen. The prone pressure method of artificial respiration, described by Schafer in 1903, is the best for lay use. The face down position, coupled with the pressure used, provides more certain and better drainage of the air passages than is possible for the layman provided with any sort of mechanical device. In the Silvester method, in which the chest is stretched into fullest possible passive expansion by bringing the arms into full extension above the head, the patient is served more by the inherent elasticity of all the tissues and less by muscle tone. The physiologic soundness of the Silvester method is, however, negated by the position of the patient on his back, which does not favor drainage from the mouth and throat, and even more by the fact that the inspiratory expansion of the chest attained by arm extension may be too slight to provide an adequate minute volume. However, for a person with an open wound of the abdomen or for a woman in the last stages of pregnancy the Silvester method may have to be used. The author describes the discovery and mode of action of the tilting method of Eve. He regards the Bragg-Paul pulsator as the best of the many methods which operate by mechanical imitation of the prone pressure method. Occasional successes and mechanical attractiveness of the blow and suck machines do not overbalance physiologic unsuitability. The value of oxygen and carbon

dioxide in stimulating breathing is evaluated. When the respirator was first introduced, it seemed as if a way had been opened for saving almost all the victims of acute poliomyelitis. This has not proved to be true, and if the first patient had had bulbar poliomyelitis instead of a spinal type ideal for treatment, enthusiasm for the respirator would have been less. The respirator will always save the lives of some patients. There are a larger number it will not save. The Cuirass type respirators give the patient freedom and they make nursing care far less difficult, but they do not work well unless some ability to breathe is retained. The respirator enclosing the entire body is capable of giving good ventilation in the presence of complete respiratory paralysis.

Clinical and Radiologic Studies of Pulmonary Mycosis.

—Johnston and Heydemann report several cases of mycotic infection encountered in a period of eight months. They stress that classification of yeast infections is a difficult procedure. Literature dealing with mycotic infections of the lung demonstrates little, if any, difference between the history, physical findings, pathology and sequelae of the various types of yeast infection. The reported cases demonstrate some of the difficulties encountered in evaluating the importance of yeast in the sputum. There may be a pure infection; there may be a secondary infection which assumes a primary role; the yeast may be an incidental finding of no clinical significance; it may be a contaminant from a receptacle. The authors feel that yeast infections are much more prevalent than ordinarily thought. As proved in the literature and in the cases reported, too many mycotic infections go unrecognized until shortly before a terminal condition exists. The recognition of mycotic infections of the lungs is in great part the responsibility of the roentgenologist. He must stimulate further study to eliminate or prove the presence of a mycotic infection.

March Fracture.—Carlson and Wertz point out that, although march fracture shows the highest incidence in the foot, it is occasionally encountered in other bones. Their report is based on 70 cases referred to the roentgenologic service of Brooke General Hospital, Fort Sam Houston, Texas, from January 1942 to April 1943, comprising 66 involving the metatarsals, 3 the femur and 1 the os calcis. Practically all cases presented varying degrees of periosteal reaction, while only 31 showed definite fracture lines. The greatest amount of callus appeared from one to two months after the onset of symptoms. Of the 66 men with metatarsal fractures, only 5 were placed on limited duty. Of the remaining 61, 11 received treatment in the outpatient clinic, consisting chiefly of arch supports, proper fitting of shoes and return to full duty. The other 50 patients were hospitalized, treatment consisting in the application of a plaster walking boot for an average of three weeks, followed by ten to fourteen days of physical therapy and proper arch supports. All 50 returned to full duty. All 3 femoral fractures involved the distal portion of the shaft with no displacement. One man returned to full duty and 2 were placed on limited duty. The patient with an os calcis fracture was likewise placed on limited duty. A diagnosis of march fracture may be made in many cases on the basis of periosteal proliferation, even in the absence of a fracture line. This condition is an example of pseudofracture. The all important factor in diagnosis is to avoid a mistaken interpretation of malignant bone tumor, leading to amputation or other unnecessary radical therapy.

Ligation of Thoracic Duct and Posthemorrhage Plasma Protein Level.—Co Tui and his associates reported in a previous communication that after hemorrhage the concentration of proteins in the thoracic duct lymph undergoes a considerable increase. It was suggested that the lymph serves an important role in the compensatory mechanism of hemorrhage, not only as a pathway for fluid, but also as a source of protein replacement. The present work is an attempt to assay the role of the thoracic duct, the principal lymph collecting channel, in the maintenance of the plasma protein level after acute hemorrhage. The posthemorrhage hematocrit and plasma protein values were determined in two groups of dogs, one with the thoracic duct ligated and the other with the thoracic duct intact. In the group with the intact thoracic duct the prehemorrhage level of plasma proteins was achieved in from twenty-four to forty-eight hours. In the group with the thoracic duct ligated this level was not reached until after eight days. On the basis of this finding and on the basis of the finding previously reported of increase in protein concentration in thoracic duct lymph following hemorrhage, it is postulated that the thoracic duct and, therefore, the lymphatic system is an important pathway not only for the return of proteins from the capillary filtrate to the blood but also for the mobilization of proteins from protein depots in the body.

Relation of Vitamin C to Anesthesia.—Beyer and his associates aimed to determine (1) the effect of anesthesia on the vitamin C content of plasma and (2) the effect of C avitaminosis on the animal's response to anesthetic agents. The anesthetics used were diethyl ether, vinethene, chloroform and cyclopropane. The first three agents were given by the "open drop" technic to 8, 6 and 12 dogs respectively. The animals used for the "open drop" anesthetizations were not intubated. None of the animals were given premedication. All the dogs were maintained at light surgical anesthesia for forty-five minutes. Six dogs were anesthetized by rebreathing a cyclopropane-oxygen mixture from a 5 liter rubber bag. Closed system anesthesia with diethyl ether was employed for 12 dogs. Guinea pigs were used to study the effect of the vitamin C content of an animal on its response to anesthesia. During and at least for the first seven hours following a forty-five minute period of anesthesia the dog plasma ascorbic acid level increased noticeably. Subsequently the plasma level fell within twenty-four hours to below the preinduction control levels. These observations held for cyclopropane, ether, vinethene and chloroform independently of the mode of anesthetization. This effect was due to the anesthetic agent and not to an inadequate oxygen intake, which tended only to reduce the rate and extent of the mobilization and to decrease or abolish the twenty-four hour fall in plasma ascorbic acid level. The initial mobilization and secondary depletion of plasma ascorbic acid which the authors observed fits in with the results of others. It is apparent that ascorbic acid is readily released from some source under the influence of anesthesia, but there is no explanation as to how

it is contained in or released by tissues. While inadequate tissue oxygenation is not responsible for the mobilization or depletion of the plasma vitamin C level, it does somehow quantitatively influence the extent of these phenomena, tending to diminish both fluctuations. Vitamin C deficiency caused guinea pigs to be more quickly inducted into anesthesia and more profoundly depressed by a given concentration of ether, chloroform or vinethene. The vitamin C deficient animals recovered slowly, if at all, from a duration of anesthesia which had little apparent after-effect on guinea pigs that had received the same scorbutogenic diet but which were injected with 30 mg. of ascorbic acid daily.

Deep Quiet Venous Thrombosis in Lower Limb.—Thrombosis of a quiet type (phlebothrombosis) commencing in the deep veins below the knee is the source of most nonobstructive processes threatening pulmonary embolism as well as most obstructive inflammatory ones responsible for painful swelling of the whole lower limb (thrombophlebitis). Thrombophlebitis of the fully obstructive type presents no indication for operations but rather for release of the associated vasoconstriction by lumbar sympathetic block. It is desirable and usually possible to distinguish an early stage of quiet, deep venous thrombosis when the process is still confined to the lower leg or has given rise to an unattached propagating thrombus in the popliteal and femoral veins, threatening pulmonary embolism. An advanced stage of quiet, deep venous thrombosis, more or less adherent but not obstructive, can also be distinguished. Thrombosis will often have propagated above the inguinal ligament into the external and, occasionally, especially on the left, the common iliac vein. With such a process, thrombosis of the deep veins among the muscles of the thigh (profunda femoris system) is usually associated. Thrombosis in these deep veins may even be present when no thrombus is found on exploration of the superficial femoral vein below the profunda. Though interruption of the common femoral vein offers a considerable degree of protection against subsequent serious pulmonary embolism, it cannot give the assurance of a yet higher division, for example, in the common iliac vein. If the common iliac vein is divided, blood can escape via the common femoral through the deep epigastric, the deep circumflex iliac and particularly through the hypogastric vein. It may pass by way of this last channel through rectal vessels into the inferior mesenteric vein or to the opposite side of the pelvis, and in women an additional collateral field is offered by the uterine and ovarian veins. Clinical experience indicates that while serious venous congestion and swelling sometimes follow interruption of the common femoral vein when the superficial and deep femoral systems are partly filled with adherent thrombus, section or ligation of the common iliac vein seems to leave no such troubles behind. Homans presents observations on interruption of the vena cava. This operation is probably indicated in the presence of bilateral thrombosis, which is believed to have arisen in the main venous stem, on both sides, to or about the level of the inguinal ligaments. It is to be preferred to separate ligation of each common iliac vein.

Canavalin, New Enzymatic Bactericidal Agent.—Farley directs attention to his discovery of a new enzymatic bactericidal agent called canavalin. He describes the method of its preparation, experimental data showing its in vitro action and certain preliminary information as to its clinical use for patients. Canavalin is a mixture of an enzyme and a co-enzyme solution separately extracted and mixed. The enzyme portion is an extract of jack bean (*Canavalia ensiformis*—8). It also has been extracted from soy beans, liver and white potatoes. The jack bean is the best source. The co-enzyme portion of canavalin is associated with the vitamins of the water soluble B group. Thiamine and riboflavin are used to produce in vitro a supply of co-enzyme. This co-enzyme is called "vitatropin" and has the physical characteristics usually possessed by a co-enzyme—thermostability, filtrability and the property of being precipitated from a watery solution by an organic solvent. Both enzyme and co-enzyme have been found by the author to be present in normal blood. In vitro studies revealed that canavalin renders both gram positive and gram negative organisms incapable of growth. The author reports 13 cases of *Ishtar* pneumococcal pneumonia treated with canavalin. Every case showed a definite drop in temperature.

Acetylcholine Synthesis and Myasthenia Gravis.—Trethewie and Wright investigated the effect of thymic extract on the synthesis of acetylcholine. An increase in acetylcholine synthesis was detected when "normal" thymus was added to brain extracts. A decrease in acetylcholine synthesis was observed when thymus from a severe case of myasthenia gravis was added to brain extract. Three likely explanations of the deficiency in myasthenia gravis are suggested: excess destruction of acetylcholine by esterase, defective utilization of acetylcholine and defective synthesis of acetylcholine. The authors present evidence in support of the rationale of the removal of the thymus in myasthenia gravis.

Genetics of Retinoblastoma.—According to Griffith and Sorsby retinoblastoma is a rare tumor. They say that at the Royal Eye Hospital, London, there were seen 59 children with retinoblastoma during the fifty years 1894-1943, and among these there was only one familial group. The pedigree of this familial group has been reported in part on previous occasions, but it is now possible to extend and amplify the previous observations of retinoblastoma in two generations to the observed occurrence of this condition in a member of the third generation. Following brief histories of the 6 affected members of this familial group the author stresses the early age at which the tumors occurred and the great tendency to bilateral involvement in this family. In only 1 of the 6 patients has the lesion been unilateral. After reviewing observations on sporadic retinoblastoma in which the incidence of bilateral involvement is much lower, the authors cite reports from the literature on retinoblastoma in sibs with clear antecedents. These reports

show that the mode of inheritance is irregularly dominant. The authors suggest that it is possible that hereditary retinoblastoma is a distinct histologic entity different from the sporadic types.

Control of Scabies by Soap Impregnated with Tetra-Ethylthiuram Monosulfide.—Gordon and his associates show that tetraethylthiuram monosulfide ("Tetmosol") when combined with soap in 5, 10 and 20 per cent dilutions retains its sarcopticidal properties. In rat scabies due to *Notoedres*, tetmosol soap produced a local therapeutic effect when used daily or weekly, the local infection being cured in some cases, the mite population being reduced in others. Six men suffering from *Sarcoptes scabiei* infection received five to six baths with 20 per cent tetmosol soap on successive days; all were cured. A further series of 110 men received three baths with 20 per cent tetmosol soap over a period of a week. All remained under observation for at least six weeks, at the end of which period 88 were found to have been cured and 22 to have relapsed. Although it has been shown that the repeated use of tetmosol soap cures a high proportion (80 per cent) of cases of scabies, the soap is unlikely to supersede any of the standard methods employed which result in more than 90 per cent cures. On the other hand, the simplicity of supplying a tablet of soap and instructing the patient to use it when bathing suggests the possible value of the soap in communities which have become disorganized as a result of war and in which it is not practicable to employ standard methods of treatment. Generalized use, however, will be possible only if dermatitis does not follow prolonged use of the soap. The authors have shown that the incidence of dermatitis following the use of the soap for short periods is low, and that it was low also among a small number of people tested over a prolonged period; but no estimate can be made of the risk of dermatitis until an extensive trial with a large number of individuals has been carried out.

Carrier State in Sonne Dysentery.—The severe outbreak of dysentery described by Hailwood occurred in an artillery regiment in July and August 1943. At least 1 Sonne positive case was found among the personnel in each cook house, but only 1 man was found whose history of diarrhea was outside the limits of the incubation period. In August 1942 he had been admitted to a camp reception station with acute enteritis, pyrexia, colic and frequent stools containing blood and mucus. In November 1942 he was posted to this regiment and in February 1943 was employed in the sergeants' quarters. His duties included providing the sergeants with cups of tea, bread and butter, and so on. At this period there was a mild outbreak of enteritis in the regiment, 80 cases in all, of which the majority were sergeants. For some months he was then employed on the guns, but on July 7 he was detailed for duty as orderly in one of the regimental cook houses. His job was mainly cutting bread and butter. The first cases occurred about July 20 and were among the battery personnel served from this particular cook house. It is certain that in the course of his duties this man visited the other regimental cook houses on numerous occasions, and thus infection would be conveyed to food and personnel in them, with consequent spread of the epidemic to the remaining two batteries. He did not so visit the permanent staff cook house, and no cases occurred among

the personnel served from there. This man had had no symptoms since his moderately severe attack twelve months previously, but his stool showed a heavy infection of *Bacterium sonnei*. The removal of all infected cooks from the cook house immediately stopped the outbreak. The opinion is put forward that the so-called symptomless carrier of *Sonne dysentery* is common but that a history of diarrhea at some time in the past can usually be obtained.

Narcoanalysis with Nitrous Oxide.—Rogerson cites disadvantages of narcoanalysis by means of barbiturates and says that during the past twelve months a way has been found of overcoming these objections by the substitution of inhaled nitrous oxide for intravenous barbiturates as the anesthetic agent. The Minnitt obstetric gas-air analgesia apparatus proved ideal. The flow of gas is regulated by the patient's breathing, so that there is no waste. The patient himself controls his intake of gas and can stop at any moment; fear is thus almost entirely eliminated. During the whole of the induction period gentle suggestions are given that he is becoming relaxed, that painful ideas will come more readily to his mind and that his thoughts are flowing easily and without restraint. As soon as he drops the mask he is urged to express whatever comes into his mind. In the case of a hysterical fugue he is told that he will relive the forgotten incidents. The author used this method with a considerable number of patients and reports 2 representative cases. He thinks that other methods of narcoanalysis could not have achieved similar results without a far greater expenditure of time. The availability of narcosis "on tap" in the consulting room, ready to be used at any moment in the course of analysis, is a great advantage. Patients themselves express a strong preference for the nitrous oxide technic; when the two have been used in a single case, access to hidden mental conflicts is fully as effective with gas as it is with a barbiturate.

Tuberculosis Disclosed by Fluorography.—Brooks says that fluorography has made possible diagnosis of pulmonary tuberculosis on a scale far transcending anything previously achieved among the apparently healthy, and the yield of cases with minimal disease is considerable. Fluorography of 479,373 apparently healthy male personnel of the Royal Navy showed that 6,077 (12.7 per thousand) had radiologic signs of adult type pulmonary tuberculosis. In 47.9 per cent of these the lesion was "minimal." Of 23,344 of the female personnel 213 (9.1 per thousand) had similar evidence of tuberculosis, and the lesion was minimal in 55.4 per cent of these. Similar investigations among civilians will no doubt bring to light large numbers of cases of pulmonary tuberculosis of this slight degree, raising difficult problems of disposal and treatment. In some of these minimal cases the disease is arrested or is retrogressive, but in others it is progressive. Careful study is needed to decide whether the infection is active, and investigation in a hospital is essential. When 2,911 sailors with minimal lesions were first studied in a hospital 16 per cent showed evidence of active infection, while in 63 per cent the disease appeared to be inactive

but the stability of the lesions was doubtful. In 21 per cent the disease was arrested. Naval personnel with apparently inactive minimal tuberculosis have been placed on light shore duties and kept under observation. Study of these cases shows that the younger the patient the more likely the disease is to become active and the relapse to be serious. Observations indicate that a diagnosis of apparently inactive minimal tuberculosis in males under 50 should imply outpatient supervision, together with regular inpatient reexamination during the next two years. For patients under 30 this observation should probably last longer. Supervision should be combined with appropriate modifications in the patient's mode of life.

- *Eosinophilia in Tropical Disease: Experiences at an Australian General Hospital. T. E. Lowe.—p. 453.
*Complement Fixation Tests in Meningococcal Infections. J. M. Bonnin.—p. 456.
Fee Principle and Medical Organization. A. E. Brown.—p. 460.

Eosinophilia in Tropical Disease.—Lowe and his colleagues studied the blood picture of men returned from service in tropical areas. Most suffered from more than one tropical illness; combinations of malaria and helminth infections were frequent. Observations were made on the effects of tropical diseases on the eosinophil picture. For comparison the eosinophil counts of normal subjects were obtained. The average reading of the eosinophil count in the control group was 145 per cubic millimeter and the range was from 0 to 700 per cubic millimeter. In 100 patients convalescent from malarial attacks the range of the eosinophil counts was between 0 and 1,350, with an average of 250 per cubic millimeter. Observations in additional selected cases suggest that the upper limit of eosinophilia in these cases may be of the order of 1,750 cells per cubic millimeter. Eosinophilia diminished as time progressed but lasted for at least eight weeks. A pronounced fall by some 50 per cent in the number of circulating eosinophil cells occurs twenty-four to thirty-six hours before the onset of malarial symptoms. After the febrile period, in cases in which treatment is given, the eosinophil cell count rises and regains its previous level in about ten days. In hookworm infection the eosinophilia was due to the presence of adult worms in the intestinal canal. It reached an average figure of 1,800 cells per cubic millimeter. After effective treatment, in two thirds of the cases the eosinophilia has disappeared within four weeks, but in the remaining one third it has persisted for much longer periods. Malaria convalescents with *Trichocephalus* infection revealed a range of eosinophil cell counts between 240 and 1,700 cells per cubic millimeter. Although the average of these figures is higher than that for subjects convalescent from malaria, it is within the range of postmalarial eosinophilia, so that *Trichocephalus* cannot be considered as a frequent cause of significant eosinophilia. The patients with *Strongyloides stercoralis* infection all had pronounced eosinophilia, but they either had coexisting infection with other helminths or were convalescent from malaria. However, the eosinophil cell count did not fall during the weeks of observation, as would have been expected if the postmalarial phase was contributing greatly to the condition. Cases of infection with *Ascaris lumbricoides* are associated with eosinophil cell counts of the same order as those accompanying *Strongyloides* infection. Under the heading of unexplained eosinophilia the authors say that 14 patients convalescent from malaria have shown a persistent eosinophilia for which no adequate explanation can be offered. They think that in malaria and in the helminth infections studied two different factors are concerned with the production of eosinophilia: (a) a nonspecific factor similar to that present in bacterial infections and (b) a specific factor due to helminth infection.

Complement Fixation Tests in Meningococcal Infections.—Bonnin shows that a close morphologic cultural and serologic relationship exists between meningococci and gonococci. It is known that a positive response to the gonococcus complement fixation test may be obtained in cases of meningococcal meningitis. The object of this investigation was to determine whether this test would be of use in the diagnosis of obscure meningococcal infections. The gonococcus complement

fixation test and the meningococcus complement fixation test were made in cases of meningitis, and control tests were performed with the serum of 58 subjects all of whom denied having had gonorrhea in the past. The gonococcus complement fixation test was found to produce a positive result in some cases of meningococcal infection. It also produced a positive response in 2 of 57 control cases. Thus it should not be regarded as absolute evidence of gonococcal infection. The meningococcus complement fixation test performed with two varieties of antigen was found to be too open to false positive results to be of any diagnostic value. The gonococcus complement fixation test may be used as an aid to diagnosis in obscure cases of meningococcal septicemia. The result should be interpreted in association with the clinical picture. The gonococcus complement fixation test may show that chronic meningococcal septicemia presenting in other than the well recognized form is more common than is generally realized. Though it cannot be used as the sole diagnostic criterion, it may be used as an indication for chemotherapy.

Incomplete Glaucoma: Study of Glaucoma Without Hypertension. R. Weekers.—p. 316.

Choroideremia.—Goedbloed states that in patients with choroideremia the external examination of the eyes does not reveal anything abnormal. The media are clear. The characteristic alterations are found in the background of both eyes. With the exception of the optic disk and the region of the macula the whole fundus shows a grayish, or greenish white color which gives the impression of almost complete absence of the pigment layer of the retina and the choroid. The term choroideremia is probably a misnomer, but it is impossible to say so definitely because of the complete lack of histologic information about this rare condition, of which only 34 cases have been reported in the literature. The author discovered this condition in a man aged 38. He had the opportunity to subject to ophthalmologic examination also the patient's mother and only sister, whose fundus condition is best characterized as nonsyphilitic pepper and salt fundus. Discussing the hereditary transmission of choroideremia, the author reviews some reports from the literature, particularly the report of Schutzbaeh, who, in a family that could be followed for four generations, detected 3 cases of choroideremia and several cases of a fundus condition that closely resembled syphilitic pepper and salt fundus although the Wassermann test in all cases was negative. This picture was quite identical with that found in the author's female patients. He concludes that choroideremia has an intermediate gonosomal (sex linked) heredity.

- *Importance of Study of Bone Marrow, Especially of Megakaryocytes in Hemorrhagic Diseases. L. Sánchez Yllades and A. Ramírez Mendoza.—p. 223.

Bone Marrow Megakaryocytes in Hemorrhagic Diseases.—Sánchez Yllades and Ramírez Mendoza report 60 cases of hemorrhagic disease, the majority in children. Special importance is given to the number of megakaryocytes in the bone marrow and of platelets in the peripheral blood, as well as to the morphologic changes of these cells in the diagnosis of hemorrhagic diseases. The number of megakaryocytes in the bone marrow and of platelets in the peripheral blood in thrombopenic purpura (including the megakaryoplthitic and pannyeloplthitic forms) and also in hemorrhagic leukemia is diminished. The number of megakaryocytes is increased in megakaryocytic purpura. The megakaryocytes and the platelets show morphologic changes in both the megakaryocytic and the megakaryopenic forms of thrombopenic purpura. In the various forms of hemorrhagic diatheses and purpura which are due to disorders of blood coagulability the number of blood platelets may be normal, increased or diminished, whereas the number of megakaryocytes is either normal or increased. Diminution in the number of megakaryocytes in these forms indicates aggravation

of the hemorrhagic diathesis or of hemorrhagic purpura. The former include the avitaminotic, the allergic and the toxic and infectious types of endothelioses and telangiectatic and nervous purpura, whereas the latter include hemophilia, fibropenia and hypothrombinemia. The estimation of the megakaryocytes is of diagnostic and therapeutic value in the types of hemorrhagic disease mentioned.

Küntsch's Nailing of Fracture of Forearm. R. Maatz.—p. 278.

Problems of Exophthalmic Goiter.—Ljunghusen calls attention to the fact that cases with postoperative and spontaneous thyrotoxic crises present the same aspect: rapid pulse and rise of temperature. The typical course is that of temporary hyperfunction followed by progressive destruction of the thyroid with its biologic sequels. The concept of the absorption of thyroxine from the wound and of its predominance in the postoperative course is erroneous. The curves of pulse and of temperature of two different groups of patients were compared. One group consisted of patients on whom operation was performed for exophthalmic goiter, whereas surgical removal of a simple goiter was performed on those of the second group. In general, the simple goiter is larger than the exophthalmic goiter and the surgical exposure is greater. The thyroxine content of the wound surface is larger, and consequently a larger amount of thyroxine is likely to be absorbed. However, only a slight increase in pulse and little rise of temperature was observed after the removal of a simple goiter, whereas a fulminant, postoperative crisis with severe tachycardia and hyperpyrexia occurred in cases of exophthalmic goiter in which preoperative iodine therapy had no effect. Compensatory adrenal hyperfunction is suggested as an adequate concept of the thyrotoxic crisis. Complete recovery resulted from subtotal strumectomy in cases of tuberculosis of the thyroid as well as in cases of exophthalmic goiter. This recovery, in spite of the unbiologic crippling of the organ, is considered as a link between the two processes which have so far been considered different in origin and character. Exophthalmic goiter after severe psychic trauma should not be considered as thyrogenic thyrosis but as severe and protracted stimulation of the thyroid gland and of the adrenals from the cerebrum. Thyrotropic hormone therapy in postoperative thyrotoxic crisis is suggested because the crisis may be caused by the increased thyroxine want, which cannot be met by the silenced thyroid. By this therapy the output of the remaining part of the thyroid may be increased, provided the remaining part is not too small and is sufficiently nourished. In case the thyrotoxic gland should contain a tuberculous agent, this will be found in the interstitial tissue. The thyroid of animals experimented on should be infected by the vascular route in a study to clarify the tuberculous origin of the disease. A borderline may be demonstrated where the picture of tuberculosis may be found on one side and that of toxic diffuse goiter on the other. Roentgen therapy proved successful in cases of mild hyperthyrosis and in severe cases in which operation had been omitted. The long duration of this therapy is its greatest disadvantage.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SENSITIVITY TO ANESTHETICS

To the Editor.—Is there any acceptable test for determining whether a patient may be sensitive to procaine hydrochloride injected into the spinal canal for anesthesia? M D, New York.

To the Editor.—While taking ether, a child aged 5, in good health except for chronically infected tonsils, broke out with a widespread urticaria. The lesions appeared shortly after the anesthetic was begun, i. e. within five minutes. No preoperative medication had been given. Within ten minutes after the injection of 3 minims (0.18 cc.) of epinephrine the urticaria disappeared. Is the reaction to be expected if the child takes ether again? Is the reaction of a serious nature? M D, Nebraska.

ANSWER—1. There is no generally accepted test to prove definitely that a patient will be sensitive to procaine injected into the spinal canal to produce anesthesia. However, there is a test which can be used which will indicate that the patient may be sensitive to procaine. The test is carried out as follows: The patient's back is exposed. Uncolored alcohol is used as an antiseptic and is applied gently. A 1 per cent solution of procaine hydrochloride without epinephrine is prepared. A syringe and wheel needle also are prepared. Isotonic solution of sodium chloride is similarly prepared with another syringe and wheel needle. One cubic centimeter of isotonic solution of sodium chloride is injected to form a skin wheal, and the reaction of the patient both locally and systemically is noted. After a few minutes (five) another wheal is raised with 1 cc. of the 1 per cent solution of procaine hydrochloride without epinephrine at a distance of 2 or 3 inches from the wheal raised with the salt solution. Again the patient is observed for symptoms of sensitivity either locally, systemically or both. If the patient shows no local difference between the wheals and is undisturbed by the injection, the probabilities are good that the drug may be used intraspinally without producing any further evidence of sensitivity. Conversely, if the patient shows no reaction to the wheal raised with the salt solution but does show a local reaction, particularly redness of the wheal that was raised with procaine, and if there are signs of dyspnea, apprehension and rapid pulse with or without a fall in blood pressure, it may be assumed that the patient is sensitive to procaine and that this agent should not be used as a spinal anesthetic.

There is considerable disagreement concerning the testing of patients for drug sensitivity. It is but rarely that the anesthetist observes symptoms during spinal anesthesia which he feels are due to sensitivity of the patient to procaine used intraspinally.

2. Blotching of the skin as a reaction with ether anesthesia is rather common in children. It usually is only temporary and is never serious. The probabilities are that if the child is given ether anesthesia again the same reaction will occur, but it is not a serious matter. Real urticaria from ether is unusual but is not serious, as was demonstrated in this case.

ALLERGY TO COLD

To the Editor.—A boy aged 11 has a deviated nasal septum. When exposed to the least chill, as from an electric fan, he gets a stuffiness in the nose, followed often by a cough. The chest is normal except for a few localized sibilant rales, which clear up on coughing; I have used the usual nasal drops and sprays. His condition is not seasonal, he does not have asthma. What treatment is advised? Should an operation on the septum be performed? If so at what age? Is there a chance that the septal condition will improve as the child grows older? M D, Alabama.

ANSWER—There is reason to believe, because of the sensitivity to cold, that this patient is basically allergic even if there is no evidence of pollinosis or asthma. Septal deviations are not likely to cause the symptoms mentioned, and an operation would not be apt to help matters. Further studies should be made to prove the presence of an allergic state. Nasal smears should be examined for the presence of eosinophils; when found in number they are pathognomonic. If on examination no secretion is present, cotton plugs should be placed in the nares for a short time to excite a flow, so that a suitable smear may

be made. From the history as given, it seems unlikely that there will be found a sensitivity to food or even inhalants; the sensitivity is probably not to heat or cold per se but to the change in temperature.

Contrast baths, such as alternating hot and cold showers, are one important method of treatment. If this is considered too drastic the patient may gain tolerance by rubbing an increasing area of the body surface with ice for a few minutes daily. Some observers have obtained good results by increasing dosage of histamine injected twice daily for two weeks and once a day for another two or three weeks.

Feinberg, Samuel M.: *Allergy in Practice*, Chicago, Year Book Publishers, 1944.

ADOPTION AND FERTILITY

To the Editor.—It is often said that a sterile married couple tends to become fertile after adopting a baby and that repeated pregnancies tend to ensue. Do the records of specialists and of clinics dealing in sterility bear out this dictum? Do they shed any light on its mechanism? For example, were the mothers' menstrual and ovulatory cycles recognizably abnormal during the sterile early years of marriage, were the fathers' sperm recognizably abnormal, and the like? Do they point to indications for advising patients to adopt a baby? Hypothalamic pathways may be involved in the endocrine phenomena that have been studied in cases of so-called freshman amenorrhea, in which luteinizing gonadotropic factors of the pituitary are suspected to be inhibited. Can similar mechanisms be demonstrated in cases of some of these babyless sterile marriages?

M D, Wisconsin

ANSWER.—Statistical studies comparing the incidence of pregnancy among previously sterile women who adopt children with the incidence of pregnancy among previously sterile women who do not are not available. If they were, they would probably show that the incidence of pregnancy in the two groups is the same. If a woman who has been sterile for some years adopts an infant and subsequently becomes pregnant, it strikes every one as a startling event and is long remembered. On the other hand, if the same woman had not adopted an infant and had become pregnant, the occurrence would be much less dramatic and few people would pay much attention to it. Unless evidence can be advanced to the contrary, it would seem likely that the purported tendency of sterile women to become pregnant following adoption of an infant is based not on fact but on the overemphasis which such cases receive. There is no factual evidence bearing on the relationship between the hypothalamic pathways and sterility.

INJECTION TREATMENT FOR VARICOCELE—VOLUNTARY HYPERVENTILATION WITH ALKALEMIA

To the Editor.—Are sclerosing agents used for the obliteration of a varicocele? Please refer me to technic. What are the complications? In the acute hyperventilation syndrome of the hysterical type I have found that breathing into a paper bag dramatically relieves the pain and spasm. Has this been reported before? I have been unable to find any reference in the literature available to me and want to report my case.

A. M. Winter, M.D., New York

ANSWER.—The injection treatment of varicocele is fully described in the monograph of Penn Riddle (Philadelphia and London, W. B. Saunders Company, 1940, p. 231). The most important point about varicocele is that it should be left alone unless it produces dragging pain in the testis or low back pain. Many neurotic persons suffering from a moderate degree of varicocele would be much better off if left alone. They can and frequently do develop a severe sexual neurosis.

Voluntary hyperventilation which may lead to alkalemia and tetanic contractions has been treated by ammonium chloride (Kerr, W. J.; Dalton, J. W., and Gliche, P. A.: *Some Physical Phenomena Associated with the Anxiety States and Their Relation to Hyperventilation*, *Ann Int Med.* 11:961 [Dec.] 1937). Rebreathing from a bag increases carbon dioxide in the blood and this counteracts alkalemia as long as the patient is unable to blow off the excess carbon dioxide.

DIETHYLSTILBESTROL AND MALE HYPERSEXUALITY

To the Editor.—I read in *Queries and Minor Notes* in the July 8 issue of *The Journal*, page 760, the problem submitted by George L. Kennedy, M.D., of Faribault, Minn., concerning the use of diethylstilbestrol in male hypersexuality. An article of mine entitled "Diethylstilbestrol in the Management of Psychopathological States in Males (I) Preliminary Report" was published in the *Journal of Nervous and Mental Disease* (99:928 [June] 1944). Dr. Kennedy's problem is apparently similar to my own. For approximately eighteen months a study has been in progress at the hospital, and the article mentioned constitutes the preliminary report of this study.

THE CLINICAL USE OF PENICILLIN IN GENITOURINARY INFECTIONS

CHAIRMAN'S ADDRESS

COMMANDER GERSHOM J. THOMPSON
MEDICAL CORPS, UNITED STATES NAVAL RESERVE

The Oxford investigators Abraham, Florey and their associates¹ were the first to call attention to the fact that penicillin in high dilution possesses strong antibacterial action on cultures of *Neisseria gonorrhoeae*. They also described a case of an infant afflicted with *Staphylococcus aureus* pyelonephritis in which the urine was quickly sterilized by comparatively small doses of the drug. Herrell, Cook and Thompson² described a series of 5 cases of gonorrhea in which response to treatment was dramatic. The extreme value of this drug in the treatment of infections of the genitourinary tract was further elaborated by Mahoney and his associates.³

Because of its particular value in gonococcal infections and owing to the fact that such infections are responsible for a considerable amount of disability in the armed forces, penicillin has been used in thousands of such cases during the past year or more. Through its use many service men have been quickly returned to duty. At first it was employed only in cases in which the infection resisted treatment with the sulfonamide compounds, but recently authorization for its use in all cases of gonorrhea has been granted. I report a series of cases which have been observed at a large naval hospital. In addition to cases of gonorrhea a number of cases in which treatment has been given for so-called nonspecific infection of the genitourinary tract will be discussed.

DESCRIPTION OF THE DRUG

The sodium salt of penicillin is a very fine crystalline or powdery light yellow substance. In solution it is light brown to light yellow, depending on the dilution.

Concerning the sodium salt the Floreys¹ wrote:

- This substance is extremely soluble in water but is destroyed by boiling, by acids and alkalis, by certain heavy metals, by

oxidizing agents and by enzymes produced by air and other bacteria. Penicillin is bacteriostatic and not bactericidal, at least in concentrations likely to be used therapeutically, and reliance must therefore be placed on the body defenses, both humoral and cellular, to destroy the bacteria present in a lesion while penicillin prevents their multiplication.

Steady progress in the manufacture of penicillin has resulted in an increasingly pure product. The unit value varies from 50 units per milligram upward depending primarily on the purity. It is said that pure crystalline penicillin has a strength of about 1,600 units per milligram.

The drug was originally supplied packaged in glass ampules, but on request the various manufacturers now dispense it in vacuum sealed, rubber stoppered bottles containing 100,000 units each, to which isotonic solution of sodium chloride or another diluent in the proper amount can be added. Concentration of either 5,000 or 10,000 units per cubic centimeter should be used, as neither is irritating when injected intramuscularly. Further dilution can be made from this more concentrated preparation if continuous intravenous drip administration is desired. The stock solution should be stored in the icebox between injections.

The mode of action of the drug is uncertain. Studies have shown that blood and urine concentrations are highest about an hour after intramuscular injection, while after ninety to one hundred and forty minutes the methods of testing which are in use at the present time reveal its complete elimination. A constant level in the blood seems unnecessary, quite in contrast to the requirement in sulfonamide therapy. The methods of assaying the amount of penicillin in blood and urine are still rather crude, and until the substance is synthetically crystallized in commercial quantities and some colorimetric method is worked out the estimation of blood and urine levels will probably remain inexact.

Estimation of blood levels in clinical urologic practice is unnecessary for, given a penicillin sensitive organism, the important test of whether sufficient quantities of the drug have been given is whether the patient gets well. Because of the scarcity of the product a great deal of effort has been bent to finding a minimal effective dose; but when penicillin is available in unlimited quantities optimal doses considerably higher than those now in use will prevail.

CLINICAL MATERIAL

Five hundred cases in which a diagnosis was made of gonococcal infection of the urethra or its adnexa and 100 cases in which the patient suffered from various nonspecific infections of the genitourinary tract form the basis for this report. All of the patients were of the male sex.

DOSAGE AND METHODS OF ADMINISTRATION

All of these patients were given penicillin by one or more of several methods. Most of the patients received the sodium salt of penicillin. In recent weeks the calcium salt has been used in a series of cases, and it seems identical with the sodium salt in its action. A number of dosage schedules and alterations of routes of administration seemed desirable in our early experience in order to find the easiest and most efficient methods for every one concerned. It seems desirable, avoiding too much detail, to record some of these efforts so that others may evaluate and discard various ideas which arise concerning treatment with the drug.

Intravenous Administration.—It seems logical that a continuous intravenous drip would insure a steady flow of the drug throughout the body and a steady excretion through the urinary tract. At first each patient was given during each twelve hour period 1 liter of isotonic solution of sodium chloride containing 20,000 units of penicillin. The injection was continued day and night for ninety-six hours. Thus a total of 160,000 units was administered. Later the dose was reduced to a total of 80,000 units given in 1 liter of saline solution during a period of twelve hours. Even though excellent results were obtained with both these schedules it soon became apparent that patients so treated were more of a nursing problem than necessary. Needles became dislodged, and feeding and toilet problems involved more detail than did intermittent intramuscular injection. The patients themselves preferred multiple puncture rather than attachment to the end of an intravenous tube and flask for a full day. The method was therefore discarded.

Intramuscular Administration.—Injection into the gluteal or deltoid muscles of a solution containing 5,000 units of penicillin per cubic centimeter seems to be the ideal treatment method for urologic cases. The injection of 20,000 units every three hours can be continued for many doses without causing irritation. When the strength of the solution was 10,000 units per cubic centimeter a number of patients complained of pain and discomfort, although these were not severe. The patients treated by intramuscular injection are ambulatory and can take care of themselves and do cleaning details or other work around the ward. The injections have been given by nurses and by hospital corpsmen who have been properly instructed, without the slightest complication. Thus the time of a medical officer is conserved in contrast to the requirements in the case of intravenous therapy.

Injections of 20,000 units each given every three hours until a total of 100,000 units has been given will result in a high percentage of cures. All the injections are given in a twelve hour period.

An attempt was made to reduce the number of injections by giving 50,000 units in each of two injections six hours apart, or a total of 100,000 units. This scheme failed miserably.

Intraurethral Administration.—It occurred to me that perhaps intraurethral instillation might be effective. Ten patients were treated by injecting intraurethrally 3 to 4 cc. of solution containing 250 or 500 units per cubic centimeter. A Cunningham penis clamp was used to retain the solution. This was continued for twenty-four hours, penicillin being reinjected after each

voiding. The urine cleared promptly and within twenty-four hours was crystal clear in all cases. However, three to four days later urethral discharge reappeared. Apparently, a few organisms lodged deep in Littre's glands and not reached by the solution provided a source of reinoculation, and after the usual incubation period urethritis again developed. Whether intraurethral injections repeated several times daily for a week or so would result in cure, I do not know. For obvious reasons this scheme of treatment was not tried. Whether penicillin solution injected locally after renal exposure would act as a prophylactic agent is doubtful. Perhaps it would be as effective as strong protein silver (protargol). A single injection of 20,000 to 50,000 units given intramuscularly might be quite efficient. No observations along this line have been made.

Intramuscular and Intraurethral Administration.—A group of patients, in the interest of conservation of the drug, was treated by intramuscular injection of 15,000 units every three hours for four doses or a total of 60,000 units, after which 4 cc. of a dilute solution of penicillin (250 units per cubic centimeter) was injected intraurethrally and held for thirty minutes. The results by this method were not spectacular and it was therefore discontinued.

Oral Administration.—Oral administration is generally ineffective because the drug is destroyed by the gastric acid. In cases in which there is achlorhydria, effective blood and urine concentration apparently can be obtained. Rammelkamp and Helm⁵ administered penicillin to 2 patients who had pernicious anemia and found satisfactory blood and urine concentration levels. Florey¹ found as little as 1,000 units given every three hours by mouth to an infant who had staphylococcal infection of the urinary tract quite effective.

I have tried oral administration in a small series of cases, supplementing the penicillin with large doses of sodium bicarbonate, but the results have been unsatisfactory. Quite likely some effective method of oral administration will be evolved later.

Intramuscular Injection of Slowly Absorbing Solutions.—After the great efficacy of penicillin in as short a time as twelve hours in cases of gonorrheal urethritis had been established, it was only natural to try to evolve a one injection method of treatment. The usual vehicles for insulin, such as protamine zinc and globin zinc, were considered. Those consulted advised against the use of protamine zinc on the ground that the large amount necessary would be irritating.

It might be thought that penicillin injected locally into the muscle might lose its potency in a few hours because of the body heat. However, Rammelkamp and Keefer⁶ found that fluid aspirated from the pleural and joint cavities twenty-two and thirteen hours after injection showed appreciable amounts of penicillin remaining.

In 6 cases 100,000 units dissolved in 10 cc. of 3 per cent solution of human globin was injected. In 3 cases the result was successful and in 3 the treatment failed. Immune globulin was tried as a vehicle without success. Serum albumin was used as a diluent on the ground that the very large molecule would promote slow absorp-

tion. In a series of 10 cases there were 4 failures. At the present time, therefore, a one shot method of treatment which would be suitable for dispensary or office practice seems only a hope.

RESULTS OF TREATMENT IN GONORRHEAL INFECTIONS

Routinely, a culture of the voided urine is obtained the morning after the administration of penicillin. This is twelve to eighteen hours after treatment is concluded. The next day, or about forty-eight hours after the first injection, a culture is obtained from the prostatic fluid. In practically all instances these post-treatment cultures were negative.

Studies of the purulent urethral secretion, the sediment from the centrifuged urine and the prostatic secretion by Gram's stain are very reliable methods of studying clinical response to treatment. In a number of cases specimens stained by Gram's method were studied hourly after the first injection. In many cases within

two hours the gonococci had disappeared from the urethral secretion. Within four to six hours no organisms could be found even by the most minute study. Before complete disappearance the gonococci gradually take on a deeper stain, so that they appear quite red and become greatly swollen and irregular. Many seem fused together instead of diplococci in shape. Later, stains of the urethral discharge or the centrifuged urine show a profusion of pus cells and some epithelial debris but no organisms.

The dramatic cessation of the purulent urethral discharge is the most impressive point in penicillin therapy. Within a few hours after the first injection the patient will usually note a great reduction of discharge. The following morning in most instances the urethra appears dry. However, in some cases a small mucopurulent or mucous drop can be expressed from the urethra each morning for several days or even as long as a week. This should not prompt one to treat the patient again with penicillin. Study of the sediment of the first glass urine by Gram's stain or by culture will fail to reveal gonococci and in all but a small percentage of cases in which 100,000 units is used a cure will result (table 1).

In analyzing the result of treatment it must be kept in mind that the patients who were the subject of this report were followed for relatively short periods. However, it is my impression that in extremely few cases will there be an exacerbation of a latent prostatic focus. If the culture of the prostatic secretion is negative forty-eight hours after treatment it will usually remain negative.

One important point in considering results of therapy is that at present there is no great assurance that an ampule of penicillin contains the exact amount stated on the label. It is my impression that many of these patients received much more than 100,000 units. This is not the fault of the manufacturer; rather it can be attributed to the inexact methods of assay which are now available.

It will be noted (table 1) that failure was reduced to 2 per cent when the recommended schedule of 20,000 units every three hours for five doses was employed. Further it should be emphasized that, in the cases in which the result was classed as a failure, cure was subsequently obtained by a course of injections of penicillin. In no case did the infecting organism prove penicillin resistant and necessitate other methods of treatment. If enough of the drug was given, a cure was obtained in all cases.

REINFECTIONS

Sixteen patients in this series were readmitted to the hospital several months after initial penicillin therapy because of another gonorrheal infection. They freely admitted that infection developed again only after further exposure. After critical analysis it seemed that these were bona fide cases of reinfection rather than recurrence of the old infection.

COMPLICATED CASES

Acute gonorrheal epididymitis, prostatitis or seminal vesiculitis was observed in only 10 cases in this series. In 5 of these it seemed prudent to give an additional amount of penicillin; hence a second ampule of 100,000 units was injected according to the original schedule of 20,000 units per injection. Rapid cessation of perineal or testicular pain and prompt reduction of swelling and other signs of inflammation were noted in all cases. Rectal examination disclosed rapid diminution of the size of the prostate gland, so that within three or four days the gland was practically normal in size. Cultures of the secretion at this time were reported negative, although pus cells persisted. Examination a week later showed the prostate secretion normal.

Inflammation in the joints, so-called gonorrheal arthritis, was observed in 6 cases. In 1 case the swollen knee joint was aspirated and a dilute solution of penicillin injected into the joint space. No striking benefit was noted as a result. Nor did continued injections of penicillin seem to aid in the other cases in which there was joint involvement. In all of them, however, the gonorrheal infection in the urethra and prostate quickly subsided and repeated cultures remained negative. The fluid aspirated from the joint cavities was never positive at any stage of the disease.

RESULTS IN NONSPECIFIC INFECTIONS

In 100 cases of infections in the genitourinary tract in which one or more strains of bacteria other than gonococci were isolated by culture or identified by Gram's stain, treatment has been given during the past

six months with penicillin and the results noted. It has not been possible in many cases to study the results of therapy for as long an interval as might be desirable. However, definite opinion as to the worth of the drug has been formulated. In the majority of these cases a mixture of organisms has been noted, some of which are sensitive to the action of penicillin while some of them are not. Study by Gram's stain of the urethral or prostatic secretions will reveal the disappearance of gram-positive organisms while gram-negative organisms persist.

In table 2 the cases are listed according to diagnosis and the effect of treatment. The series of cases is not as comprehensive as might be desired but, nevertheless, some idea of the worth of penicillin in such cases can be obtained.

Acute Nonspecific Prostatitis.—In the 4 cases observed the response to treatment did not seem as rapid as it was in the cases of acute gonorrheal prostatitis.

Cultures of prostatic secretion in 3 cases were reported to be *Staphylococcus albus* and in the fourth case nonhemolytic *Streptococcus*. In the latter case the acute inflammatory process was confined to the right lobe of the gland; the region was quite indurated

TABLE 2.—Nonspecific Infections Treated with Penicillin

and extremely tender, suggesting abscess, but there was no fluctuation. This patient also had keratitis. He was given fifteen injections of 15,000 units each. Almost immediate improvement of the ocular condition was noted and within a week the region in the prostate gland had changed to normal consistency and the expressed secretion contained much less pus than before and no organisms.

Chronic Prostatitis.—An excellent response was noted in 24 of the 30 cases in which a diagnosis of chronic prostatitis was made. The best indication of chronic infection in the prostate gland is the presence of pus cells and the finding of bacteria in stained smears of the expressed secretion. Cultures were made in the majority of the cases. Among the organisms reported found were *Staphylococcus albus*, *Streptococcus* (hemolytic), *Streptococcus* (green producing), *Bacillus subtilis*, *Micrococcus*, diphtheroids and *Alcaligenes fecalis*. In my experience more knowledge and a better idea of the severity of the prostatic infection can be obtained by noting the polymicrobial character and relative number of organisms in a smear stained by Gram's method than by cultures. I believe that many urologists will concur in this opinion.

Frequently gram-positive cocci are found in a smear when a culture of the same material is reported negative. For this reason in my opinion cultures provide corroborative data, but conclusions should not be based on cultures alone.

Of greatest importance is a correlation of all the symptoms and signs, including size of the gland and presence of induration. In 80 per cent of the cases in which penicillin was used there was improvement—in the majority, pronounced; in only a few, moderate. How many cures were obtained is conjectural, since past experience shows that chronic prostatitis does not often remain cured, and few of the cases in this series have been followed for more than a few months. The results to date, however, are very encouraging. A reduction of the pus cell count of the expressed secretion from 150 or more cells to the high dry field down to 8 or 10 per field is the rule rather than the exception. Such results may be seen a few days to a week after a course of five injections of 20,000 units each. In some cases a second course of 100,000 units two or three weeks after the first was necessary to obtain a really striking effect.

Nonspecific Urethritis.—In 36 cases in which the diagnosis of nonspecific or nonvenereal urethritis was made, treatment with penicillin was given. Purulent urethral discharge presenting as a morning drop was the chief complaint. These patients usually had noted the infection for months prior to admission. Gonorrheal infection was first ruled out. Routine examination of the prostate and the passage of urethral sounds to detect strictures of small or large caliber were done. Urethroscopy was done in most cases. A marrow meatus was found in some instances and meatotomy was performed. In the majority, however, there was no sign of urethral abnormality other than the infection. Response to penicillin therapy in this group is not as good or as dramatic as it is in the case of gonorrheal infections. However, in the uncomplicated cases a high percentage of patients noted improvement as evidenced by reduction or cessation of discharge. Shreds disappeared from the urine in some cases in which they had formerly persisted for months in spite of all other treatment.

It should be emphasized that in any case of chronic nonspecific urethritis thorough examination should be made to detect stricture and so forth before institution of treatment.

Nonspecific Acute Epididymitis.—In 7 of 8 cases there was notable response to a course of ten injections of 20,000 units each. In the 1 case in which there was no appreciable benefit the infection developed within a few days after transurethral prostatic resection. Acute inflammation in the epididymis usually is accompanied by an infection in the corresponding seminal vesicle, and sometimes the adjacent testicle is also involved. Often an acute hydrocele forms. These patients suffer great pain and discomfort and are quite disabled. The prompt relief of pain and the rapid reduction of the tenderness and swelling were most convincing of the efficacy of penicillin. In no case was epididymotomy or other incision required.

Balanitis and Wound Infections.—In 6 cases in which there was considerable infection of a redundant, untractable prepuce treatment was by local instillation of a solution containing 250 units of penicillin per cubic centimeter. Improvement was so remarkable that circumcision was possible within forty-eight to seventy-two hours. Dorsal slit was avoided in all cases. In 2 cases wound infection following nephrectomy was quickly cleared up by instillations of 5 to 10 cc. of the

dilute solution. Apparently the antibacterial action of these solutions, when they are instilled into wounds, lasts for many hours. It has not been necessary to instill the solution oftener than twice daily. In 1 case of purulent inguinal adenitis which required incision and drainage the infection healed with remarkable rapidity as a result of instillation of penicillin solution. There was practically no drainage after the first instillation. Instillations of a few cubic centimeters once daily were continued until healing was practically completed.

Interstitial Cystitis.—In 3 cases interstitial cystitis was treated by intramuscular injection of 10,000 units every three hours for fifty doses. In addition in 2 cases intravesical instillation twice daily of 30 to 45 cc. of a solution containing 250 units per cubic centimeter was done. The patients were able to hold the solution in the bladder for an hour or two. No irritation was noted. Cultures of the urine were reported *Staphylococcus albus* in 2 cases and diphtheroids and *Staphylococcus* in the other. In none of the cases was there any benefit which could be attributed to penicillin. Subsequently intravenous injections of neosarsphenamine and irrigations of silver nitrate were given. All were benefited by this treatment.

Pyelonephritis.—As far as I have been able to determine, penicillin is equally effective in alkaline or acid urine. In several cases infection of the upper part of the urinary tract in which there was a mixture of organisms I have employed another drug such as ammonium mandelate or sulfanilamide in addition to penicillin, hoping that the combined effect would result in sterilization of the urine. Abraham and Chain⁷ have shown that gram-negative rods, including *Escherichia coli*, actually secrete an enzyme, penicillinase, which destroys penicillin. Results of combined therapy in some cases therefore might well be superior to the use of penicillin alone.

In practically all of the cases of pyelonephritis which I have seen the disease has been acute, and it is well known that a large percentage of these will recover spontaneously. It is therefore extremely difficult to evaluate the particular virtue of penicillin. In 2 cases of chronic renal infection complicated by the presence of multiple calculi not sufficiently large to warrant operation the condition was treated with penicillin. In these there was a mixture of organisms, both gram-positive cocci and gram-negative bacilli. The cocci disappeared from the urine after penicillin therapy, but the bacilli persisted. Cultures following treatment revealed *Proteus vulgaris* in 1 case and *Escherichia coli* in the other. In the case in which there was *Proteus* infection a catheter was introduced into the renal pelvis and lavage with solution G and solution M⁸ was performed. This resulted in a remarkable reduction of the number of organisms which could be found in stained smears, but two days after lavage was discontinued the bacilli reappeared in great number. No effect on the stones was observed.

I believe that penicillin will be of great value in the treatment of renal infections due to a susceptible organism when the patient is unable to tolerate sulfonamide compounds. For infants and small children suffering

from acute renal infection it should have particular value, because the risk of toxic reactions from sulfonamide compounds is greater for them than for adults.

It is possible in any case to make tests in vitro to determine the penicillin sensitivity or resistance of the particular organism. However, because of the fact that renal infections are often of mixed type a clinical trial would seem more practical than a test in vitro.

TOXIC REACTIONS

No serious toxic reactions were noted in any of the 600 cases. One patient had an elevation of temperature to 101.5 F., but this was attributed to some contaminant rather than to the penicillin. Several days after treatment 2 patients had a mild macular eruption which faded quickly. Three patients had an id reaction on the palms which very definitely was precipitated by injections of penicillin in my opinion.

Attention should be directed to the lack of local reaction, the ease of administration and the lack of any systemic symptoms even after large doses. In a number of cases in which treatment was given for conditions other than urologic disease, doses of 500,000 units during a period of twenty-four hours have been employed without toxic manifestations. Therefore in urologic cases one need not be hesitant about using much larger doses of the drug than have been suggested in this paper.

It is unnecessary to alter the diet in any way in my opinion. In cases of septicemia, chronic osteomyelitis or severe systemic infections, changes of diet might be important while the drug is being administered, but in urologic practice any change of diet is unnecessary and superfluous.

CONCLUSIONS

1. Penicillin is a particularly valuable drug for the treatment of gonorrhea. The most practical method of administration is the intramuscular injection of a solution containing 5,000 or 10,000 units per cubic centimeter. Doses of 20,000 units injected every three hours until 100,000 units has been given will result in cure in fully 98 per cent of the cases.

2. Penicillin is unstable in solution and at room temperature will rapidly lose its antibacterial power. Solutions should be freshly prepared and kept in the icebox between injections.

3. Penicillin is an extremely useful drug in the treatment of various nonspecific infections of the genitourinary tract. If the infection is caused by penicillin sensitive organisms the result of treatment is excellent. In most cases, however, the infection is of mixed type and the result of therapy is not dramatic. Nevertheless it is worth while. Penicillin combined with other urinary antiseptics in these cases might well be superior to other methods of treatment.

4. The results of treatment in urologic cases can be determined well by making repeated Gram's stains of the urethral or prostatic secretions or of the sediment of the centrifuged urine.

5. Treatment with penicillin is so devoid of toxic reaction that there is no reason to outline difficult schedules or to use complicated methods. The physician need not be fearful of using too much of the drug and should follow the dictum that the dose of any medicine is "enough."

PENICILLIN IN THE PREVENTION AND TREATMENT OF CON- GENITAL SYPHILIS

REPORT ON EXPERIENCE WITH THE TREATMENT OF
FOURTEEN PREGNANT WOMEN WITH EARLY SYPHILIS
AND NINE INFANTS WITH CONGENITAL SYPHILIS

J. W. LENTZ, M.D.

NORMAN R. INGRAHAM JR., M.D.

PHILADELPHIA

The treatment of the pregnant syphilitic woman and of the congenitally syphilitic infant with weekly injections of neoarsphenamine or mapharsen supplemented by a bismuth preparation, although eminently satisfactory from the standpoint of both preventive and curative medicine, still has several aspects in which improvement may be expected. These facts have led us to try penicillin in the treatment of these conditions with the hope that it might be possible to eliminate some of the deficiencies in present day therapy.

Included among the factors in the prevention and treatment of congenital syphilis which we would like to see improved by the discovery and application of new drugs and new technics, the following may be mentioned:

1. Arsenotherapy is relatively toxic. Although, generally speaking, arsenicals are well tolerated and safe to use in the average case,¹ reactions do occur which interfere with treatment or at times preclude their use entirely, and death of the expectant mother has been known to result from chemotherapy for syphilis during pregnancy.² A safer drug is accordingly a desideratum.

2. Antepartum syphilis treatment, as usually administered, is not curative of the mother's syphilis. For this purpose it must be continued for long periods post partum and, in order to prevent the birth of syphilitic infants, it must usually be repeated in each subsequent pregnancy.³ It is true that intensive arsenotherapy (five day drip) has been employed successfully for a small number of pregnant women with early syphilis,⁴

but this approach to the prevention of congenital syphilis is not generally accepted.⁵ It is relatively toxic and must be considered dangerous in routine medical practice and a questionable choice even under ideal circumstances. One of the extremely difficult public health and social problems in this field has been the postpartum observation of the mother for syphilis.⁶ A drug which would be curative during the pregnancy of both mother and child is to be wished for.

3. Although several short series of cases appear in the medical literature in which 100 per cent normal infants have resulted from adequate arsenotherapy of the syphilitic pregnant woman,⁷ larger series show a definite residuum of syphilitic infants sometimes in spite of ideal therapy.⁸ This is usually in the neighborhood of 5 to 8 per cent diseased infants if the treatment has approached accepted adequacy. Particularly difficult cases for intravenous arsenotherapy are those in which treatment is not commenced until the latter months of the pregnancy, particularly if the expectant mother is in the early stages of her disease.⁹ Under such circumstances a very high percentage of infants are syphilitic in spite of therapy. This problem is bound to the permeability of the placenta, to the arsenobenzene derivatives and to the effectiveness of the uncertain quantities of the drug which do pass from the mother to the child after the fetus in utero has been infected.¹⁰ In such instances the placental membrane must be traversed by a curative dose of the drug if a normal infant is to be born. An effective spirillicide which will readily traverse the placenta is still to be hoped for.

4. Three principal factors still complicate the treatment of infantile congenital syphilis. They are the extreme caution with which therapy must be inaugurated when the disease is manifest,³ the prolonged course of treatment essential to cure¹¹ and again the residue of patients who are not cured by arsenotherapy and bismuth, a proportion which increases rapidly with the age of the infant at the time treatment is begun.

In addition, the treatment of the syphilitic pregnant woman and, more than this, the observation of the treated syphilitic woman who subsequently becomes pregnant are both critical experiments in the testing of the effect of the new drug. Since the fetus is intimately associated with the mother and is almost uniformly infected if the maternal syphilis is active and untreated, these circumstances give the counterpart in the human being of the inoculation test of cure in the rabbit or other experimental animal. In the woman the

ultimate test of cure of her syphilis will always remain her ability to give birth to normal children in subsequent pregnancies, even though no further antisyphilitic treatment is administered.

MATERIAL

The cases used for this report consist of 12 pregnant women with symptomatic early syphilis and 2 with early latent syphilis and 9 infants with early congenital syphilis. None had received any type of antisyphilitic therapy prior to treatment with sodium penicillin.

The first pregnant woman started treatment on Nov. 19, 1943 and was delivered March 20, 1944. The maximum period of observation, therefore, at the time of writing this paper (June 29, 1944) has been for the mother seven and one-half months and for the newborn infant three months. Seven of the mothers had not delivered at the time this material was analyzed.

The first infant with congenital syphilis commenced his treatment on Feb. 8, 1944, so that in this case the maximum period of observation is about four months. All patients treated have been included in this report in order to evaluate the initial response to therapy and the contraindications to treatment, if any.

The material has been drawn from the clinics and wards of several of the Philadelphia hospitals¹² and observations were made by members of the University of Pennsylvania Penicillin Panel under the chairmanship of John H. Stokes, M.D.

RESULTS

In the Pregnant Syphilitic Woman and Her Child.—The clinical response to treatment and the result of delivery in each of the 7 pregnant women who have reached term is summarized in table 1. This table also shows graphically the serologic response to treatment of both mother and child. In each instance an apparently normal infant has resulted at full term except in case 76, in which the infant was considered to be premature because it weighed only 4 pounds 10½ ounces (2,112 Gm.) at birth, but it appeared otherwise healthy. Dark field examination of the umbilical vein was negative in 5 instances and not performed in 2. Roentgenograms of the long bones during the neonatal period performed in 4 cases at birth and repeated at the age of 6 weeks or later in every instance were all normal. Three of the infants had positive cord and neonatal blood serologic tests in every case with quantitative titers either equal to the mother's or lower. In case 13, the mother's blood serologic test was 4 Kline units at birth and the infant's ½ unit; in case 25 the mother's titer was 32 units at birth and the infant's 16 units; in case 49 the mother's and infant's titers were both 64 units.

In each instance in which the infant's blood serologic test was positive at birth it has fallen sharply postnatally

12. The Hospital of the University of Pennsylvania supplied 8 cases for this study, the Philadelphia General Hospital 11 cases, the Children's Hospital 2 cases, the Pennsylvania Hospital and the St. Luke's and Children's Medical Center each 1 case.

FOOTNOTES TO TABLE

Symptomatic clinical response in the mother in each instance was immediate.

* Given in Kline units for sake of uniformity. Tests were checked with quantitative Kolmer Wassermann and Eagle flocculation with comparable results.

† The seven mothers, as of Sept. 28, 1944, have been followed a maximum of 286 days post penicillin (average 216 days). All have become seronegative except case 4 and case 49 (each less than 1 unit of reagin) and case 71, which retains 32 units. All are clinically normal. Each of the infants has remained clinically and serologically normal for a maximum period of 163 days post partum (average 124 days). One of the fourteen pregnant women mentioned in the text, who was treated with 1,200,000 units of penicillin, developed infectious relapsing lesions just prior to delivery, 122 days post penicillin. (Kolmer Wassermann.)

and has become normal in less than one month. In the period of observation, none have shown any tendency to revert to positive. The remaining 4 infants were born with negative blood serologic tests for syphilis and have remained seronegative up to the time these data were compiled. In the period of observation, only 3 of the mothers have become seronegative: Patient 15 was found to be seronegative ninety-five days post penicillin and forty-seven days prior to delivery, and patient 39, who has not yet reached term, was found to be seronegative seventy-seven days post penicillin and has remained so for two months. Patient 25 was found to be seronegative sixty-nine days after delivery.

In the 7 cases in which delivery has occurred penicillin treatment was started 142, 121, 103, 93, 76, 73 and 47 days respectively prior to delivery or from the fifth to the eighth lunar months of the pregnancy respectively. In no instance was treatment instituted

after the commencement of penicillin treatment. In 2 cases threatened abortion, as evidenced by spotting and by lower abdominal cramps, occurred in 1 instance in eighteen hours and in the second case in forty-eight hours after the start of penicillin therapy. The drug was immediately discontinued but resumed in full dosage in twenty-four hours without a recurrence of symptoms. This the only type of reaction that developed in any of our pregnant patients could perhaps be considered to be a form of therapeutic shock (Hersheimer reaction) occurring in a grossly diseased area and would possibly fall in the category of placental shock, described in the older literature and occasionally seen after arsenotherapy administered without preparatory treatment to pregnant women with active syphilis. It would suggest that, in the present state of our knowledge at least, it might be best to reduce the penicillin dosage by three fourths to one half during the first

TABLE 2.—Summary of Case Records of Five Infants with Early Congenital Syphilis Treated with Penicillin

Identifying Data	Initial Clinical Findings	Weight on Admission	Total	Per Pound of Body Weight	Duration of Observation After Penicillin	Result
Case 43 P G H Race—B Sex—♂ Age—42 days Treatment started 2/8/44	D F +; skin lesions, snuffles, enlarged liver; roentgenogram; advanced osteochondritis and periostitis; serologic test positive, 120 units (Kline)	6 lbs. 3 oz.	100,000 units	16,181 units	99 days	Living; normal physical examination, normal roentgenogram of long bones, negative serologic test since 5/15/44
Case 47 U. of Pa. Race—B Sex—♂ Age—18 days Treatment started 2/11/44	Premature snuffles, enlarged liver; roentgenogram; pronounced osteochondritis and periostitis, serologic test positive, 128 units (Kline)	4 lbs. 7 oz.	80,000 units	18,000 units	16 days	Died 2/27/44; circulatory collapse; possible congenital heart disease; no autopsy
Case 58 Child H. Race—B Sex—♂ Age—4 months Treatment started 2/20/44	Sealing skin lesions most pronounced on palms and soles, snuffles; roentgenogram, periostitis of long bones; serologic test positive, 128 units (Kline)	12 lbs. 11 oz.	236,000 units	18,773 units	70 days	Normal physical examination; roentgenogram, periostitis disappearing; serologic test, 8 units (Kline) 6/17/44*
Case 63 U. of Pa. H. Race—B Sex—♂ Age—8 months Treatment started 3/3/44	Malnutrition; dysphagia; serologic test positive, 64 units (Kline), roentgenogram not diagnostic	13 lbs.	242,000 units	18,615 units	97 days	Normal physical examination; blood serologic test, 1½ unit (Kline) 6/5/44
Case 112 St. Luke's Race—B Sex—♀ Age—31 days Treatment started 3/29/44	Roentgenogram, osteochondritis and periostitis; serologic test strongly positive; associated gonococcal vaginitis	10 lbs. 8 oz.	111,623 units	10,451 units	8 days	Died 6/6/44; temperature elevation to 104 F.; severe diarrhea and dehydration with weight loss of 3 lbs.; autopsy; gross and microscopic findings of congenital syphilis only

All of the mothers had seropositive latent syphilis and none were treated prior to birth of the infants given in the table.

* This patient developed dark field positive skin lesions on Aug. 24, 1944. The infant never became seronegative, and blood titer rose to 2 units when relapsing lesions appeared. Mother showed no evidence of open lesions at the time of relapse in the infant and was receiving treatment with phenarsine hydrochloride and bismuth subsalicylate. This was considered to be a penicillin failure and the infant was retreated with penicillin.

prior to the midpoint of the pregnancy or in the month immediately preceding term.

Method of Treating the Syphilitic Pregnant Woman.

—Each of the pregnant women who have thus far reached term had received 1,200,000 Oxford units as her total dose of sodium penicillin, with the exception of patient 71, who left the hospital without receiving her last two four hourly injections and patient 49, who received 2,400,000 units. Three additional patients who have as yet not reached term also received 2,400,000 units. The injections were given intramuscularly, each dose in approximately 1 cc. of sterile distilled water every four hours around the clock for a period of approximately eight days. The individual four hourly dosage for 10 cases was 25,000 units and for 4 cases 50,000 units.

The clinical response of infectious surface lesions to treatment of the expectant mother was very rapid. Usually, *Treponema pallidum* disappeared, as determined by dark field examination, in less than eight hours. In no case did the dark field preparation show *Treponema pallidum* longer than twenty-four hours

thirty-six to forty-eight hours of treatment of the syphilitic pregnant woman. We have followed this suggested procedure of reduced dosage during the first forty-eight hours for the last 10 pregnant women treated and have not had an additional instance of threatened abortion.

In Infantile Congenital Syphilis—Nine patients with early congenital syphilis were treated with sodium penicillin. The results in the 3 cases which have been followed long enough to make any report possible are given in table 2. Two deaths possibly not due to penicillin treatment which occurred among 9 cases thus far treated are also included in this table. The 3 living infants followed for 99, 97 and 79 days respectively after administration of sodium penicillin all became clinically normal to physical examination.

All 3 infants had relatively high blood serologic titers initially, but these dropped sharply to normal in 1 instance and to relatively low levels in the other 2 instances (½ unit and 8 units respectively) during the period of observation.

The 2 infants who showed definite roentgenographic changes of syphilitic osteochondritis and periostitis have resumed approximately normal bone development, as shown in the illustration

Dosage Employed in Infantile Congenital Syphilis.—In 6 of the 9 cases treated, the total dosage of sodium penicillin given every four hours around the clock over approximately an eight day period was between 16,000 and 19,000 units per pound of body weight. This is considerably in excess of the dosage given the majority of the pregnant women, which except in 4 cases was not in excess of 10,000 units per pound of body weight. The remaining 3 infants received respectively 2,935, 10,631 and 11,111 units per pound of body weight.

The only definite treatment reaction noted among the 7 infants who are still living was in the first infant

A Before penicillin

B After penicillin.

Improvement in syphilitic osteochondritis from penicillin therapy in case 43, in which treatment was started when the child was forty-one days old. Only the right knee joint is shown, though all the long bones had similar involvement. In A, note complete disorganization of distal femoral metaphysis and proximal metaphysis of the tibia. This area is approximately normal in B, eight or three days after commencement of penicillin.

treated (case 43 in table 2). After receiving 19,000 units of sodium penicillin in the first forty-eight hours this patient developed severe dyspnea and cyanosis, necessitating supportive treatment and the administration of oxygen. His condition remained critical during the next eighteen to twenty-four hours, during which period penicillin was withheld. The drug was then resumed in full dosage without recrudescence of symptoms and with apparently a favorable outcome. This is the only infant that thus after a ninety-nine day period has developed a completely negative blood serologic reaction

COMMENT

Our case material does not permit us to draw sweeping conclusions either as to the management of the syphilitic pregnant woman or with regard to the care of the syphilitic infant. We are of the opinion that the total dosage of penicillin used, the time dose relationship or the duration of treatment employed for our patients is not the ideal. In fact, we are experimenting with other dosage systems. On the other hand, since penicillin is now available for general medical use, it is felt highly desirable to make such factual information as exists available in the medical literature as rapidly as possible.

It is our belief that, as far as it is possible to determine with a limited number of cases, a total dosage of sodium penicillin in the same magnitude (1,200,000 units) as was originally used by Mahoney, Arnold and Harris¹³ in the treatment of early acquired syphilis in the adult is safe to use for the pregnant woman, preferably with reduced individual doses for the first thirty-six to forty-eight hours. By safe we mean that it clears the mother of infective surface lesions; with proper time dose relationship it need provoke no after-effects, and it will apparently "protect" a good proportion of the offspring from early or immediate manifestations of congenital syphilis. This is what, plus the danger of other reactions, we had come to expect of the arsenicals. Penicillin may therefore perhaps replace them. In view, however, of the demonstration of an incompletely curative result under 1,200,000 Oxford units in not less than 10 per cent of cases of early syphilis and the trend to higher dosage (2,400,000 Oxford units) on the part of some authorities and competent advisory agencies, we believe that such an advance in the total dose of penicillin is now proper and presumably safe for the pregnant woman in good general condition. By such a total dose, using a therapeutic agent with the reactionless record of penicillin, we shall, we hope, approach more nearly, if not reach, the cure of the mother with the full protection of the child.

It is not, of course, possible to say whether all the infants in the present series have escaped infection, nor will it be possible so to state short of several years of postnatal observation. It will further not be possible to evaluate the effectiveness of treatment of a syphilitic pregnant woman to prevent congenital syphilis without the analysis of much larger case material observed for a much longer time. It must also be pointed out that the permeability of the placental membrane to penicillin is at present unknown and that cases treated immediately before delivery or prior to the fifth lunar month have not as yet been reported.

There are indications that penicillin given to the mother just prior to delivery (Barksdale) is not recoverable from the umbilical vein at birth. Considering the fact, however, that untreated pregnant women with early syphilis almost uniformly give birth to dead or diseased children, we believe that it is encouraging, to say the least, that among the 14 women treated by us not a single stillbirth or neonatal death has occurred. The 7 infants delivered have, moreover, remained physically normal and seronegative for days of observation numbering 101, 81, 78, 69, 25, 5 and 1 post partum respectively.

We realize that a six months or longer period of active postnatal observation is desirable to rule out the

13. Mahoney, J. R., Arnold, R. C., and Harris, A. Penicillin Treatment of Early Syphilis. A Preliminary Report. Ven. Dis. Inform. 24: 333 (Dec.) 1943. Bloomfield, L. A., Rentsch, L. A., and Kirby, W. M. M. The Clinical Use of Penicillin. J. A. M. A. 124: 227 (March 6) 1944.

possibility of congenital syphilis. But, if the type of medical follow-up evidence which has been found satisfactory for pregnant women treated with arsenicals is acceptable for those treated with penicillin, then it is distinctly exceptional to encounter congenital syphilis which is not detectable with the use of roentgenographic and blood serologic test procedures by the end of the second month. It seems unlikely, therefore, that the 4 infants who have passed the sixtieth day of postnatal observation will develop signs of congenital syphilis in the future, though we expect to keep them under observation for a matter of years, if possible.

Infantile Congenital Syphilis.—The present state of our knowledge with respect to the ideal treatment of infantile congenital syphilis is much less exact than is our limited knowledge even of the treatment of the syphilitic pregnant woman. Not only are we uncertain that we have developed a proper and effective total dosage or time-dose relationship for the administration of a sodium penicillin to infants with congenital syphilis, but we are in addition not certain that the method of treatment employed by us is entirely safe for the small grossly diseased infant. A word of caution as to the possible dangers of indiscriminate experimentation in this field is therefore given.

It is highly possible that the severe reaction (dyspnea, cyanosis and so on) observed in case 43 would fall into the category of therapeutic shock (Herxheimer reaction). In this instance, in spite of the severity of infection in the infant, little attempt was made to reduce the initial dosage for any considerable time, even though the first three injections (i. e. the first eight hours of treatment) were reduced to one-half the calculated dosage. We are likewise not certain that either of the two observed deaths resulted from the use of sodium penicillin as such. In each instance the death could be accounted for from another cause. In case 47 a possible congenital heart lesion and in case 112 a severe diarrhea with dehydration, uncontrolled by pediatric care, were undoubtedly important contributing factors to the deaths of the infants. In treating congenitally syphilitic infants in the past, however, the reactions caused by injudicious treatment have been considered not infrequently a primary rather than a secondary cause of death.

We believe that it may be significant that each of the infants in whom severe reaction or death occurred was less than 2 months of age. All of the other infants treated were older than 2 months at the time treatment was started. They therefore had had their infections longer, were more fully adjusted to extrauterine existence, had presumably built up some individual resistance and were better able to combat any toxemia which might develop from the too rapid treatment of overwhelming infected body tissue. We are reminded forcefully that the real danger of too energetic arsenotherapy of congenital syphilis lies in these first few weeks of life when the infection is overwhelming, the nutritional state of the infant poor and its resistance to disease undeveloped. We cannot fail to remember also that for complete safety it has been shown that it is necessary to maintain reduced dosage in these cases not for a matter of a few days but often for three or four weeks. Here, then, may be a situation in which too rapid treatment with large dosage of penicillin may be injurious to the infant even though beneficial for the disease itself.

Since the cases described were treated we have observed another infant 2 months old at the inception of penicillin therapy but not reported in detail, since

treatment was completed only on June 5, 1944. This infant, which weighed 9 pounds (4.1 Kg.), was given a total dosage of 100,000 units of sodium penicillin in eight days (approximately 11,000 per pound of body weight), but the dosage was kept much reduced from the first to the third day. Five per cent of the total dosage was given in the first twenty-four hours, 10 per cent on the second and third day each and 15 per cent on each day thereafter with no untoward reaction.

In some of the older and heavier infants we have also recently given greatly reduced doses for the first two or three days of treatment without reaction. In spite of this, however, we are not certain that reduced dosage carried out for so short a period will be effective in preventing reaction in every instance if we are here dealing with the type of therapeutic paradox in the small severely infected infant which has accompanied other types of rapidly effective chemotherapy. One necessity for safety certainly stands out with increased emphasis. This is the insistence on painstaking and experienced general pediatric care as an accompaniment to penicillin therapy.

It is too soon to discuss the proof of "cure" of syphilis in women by their ability to bear normal children in subsequent pregnancies, since this is a question which can be studied only over a period of years. If the apparently normal infants born of the women with early syphilis in this study prove on subsequent observation to be nonsyphilitic, then it is a probable but not yet an established fact that these women have been cured of their disease. The most obvious conceivable exception to this supposition would be that the infection was suppressed in the mother as a result of treatment for the several months of her pregnancy in which she was carrying the child to the point where the disease was not transmitted, only to have a recrudescence subsequent to delivery.

It should also be noted that the present report deals with early syphilis complicating pregnancy. It is not certain that these observations are necessarily applicable to the greatest problem confronting the medical profession in this field, namely latent syphilis of unknown duration complicated by pregnancy. It is highly desirable, therefore, that the question of penicillin treatment of latent syphilis complicated by pregnancy be studied as soon as possible.

CONCLUSIONS

1. There are several factors in the medical treatment of the syphilitic pregnant woman and the infant with congenital syphilis which are in need of further study and improvement.

2. It was with the thought that some solution to these problems might be found through the use of penicillin that the present study was undertaken. Sodium penicillin exclusively was employed. Experience with the treatment of 14 pregnant women with early syphilis and 9 infants with congenital syphilis formed the basis for this analysis.

3. The material is reported at this time, even though incomplete, since preliminary observations indicate that sodium penicillin has a definitely good effect both on the mother and on the child in syphilis in pregnancy and on infantile congenital syphilis. Because the drug has been released for general distribution, dissemination of even our present limited knowledge seems desirable.

4. The proper total dosage and the time-dose relationship has not been worked out to complete satisfaction either for syphilis and pregnancy or for infantile congenital syphilis.

5. The limited existing data would seem to indicate, however, that total doses of the magnitude of 1,200,000 Oxford units and 2,400,000 Oxford units given intramuscularly round the clock in approximately eight days, as used in the treatment of early syphilis, are well tolerated by the pregnant woman, with the possible exception that therapeutic or placental shock may occur, to be avoided by considerably reducing the dose for the first thirty-six to forty-eight hours of therapy. The course of expert experience with penicillin in syphilis in general suggests the desirability of the higher dosage (2,400,000 Oxford units).

6. Preliminary results indicate that "cure" or suppression of the infection takes place in a number of the mothers and, that miscarriage, stillbirth and neonatal death are averted, and the infants are born apparently healthy. It must be reiterated, however, that the period of observation for either mother or child has not been long enough to be certain that they have been cured by the dosages employed. The course of the disease has nonetheless been profoundly and favorably affected.

7. Infants with congenital syphilis make a good response to dosage of approximately 18,000 units per pound of body weight. Grossly infected syphilitic infants, however, may be injured by the injudicious use of penicillin. In the present state of our knowledge their treatment should be approached with extreme caution, with reduced dosage and with great emphasis on proper general pediatric care.

THE MEDICAL TREATMENT OF PSYCHOSOMATIC DISTURBANCES

WITH SPECIAL REFERENCE TO THE GASTRO-INTESTINAL TRACT AND FATIGUE

SIDNEY A. PORTIS, M.D.
CHICAGO

While physicians in the past have given "lip service" to the emotional status of the patient, little insight has been developed into the results of emotional factors on processes of the body. The patient has often been rebuffed because his complaints were thought to be functional; he has been dismissed as a neurotic and told "go home and quit worrying about yourself." The patient who expresses his emotional difficulty in terms related to disabilities of organs may or may not be satisfied with this diagnosis. He may become the victim of varied treatment, including even multiple operations within the abdomen. Physicians should realize that a majority of ambulatory and even of bedfast patients may have altered functions that result from disturbances of the emotions. The patient who is not conscious of his difficulties presents a bizarre collection of symptoms unrelated to any determinable organic disease. The mechanisms of such syndromes are as yet little understood, even by those who use the psychoanalytic approach to their significance. Therefore, large amounts of data should be collected which will make the physician just as certain in his knowledge of the mechanisms concerned as he is in controlling well recognized organic manifestations with which he is familiar. The patient must nevertheless be treated and his problems approached in a logical manner, while laboratory and clinical observations evolve to the level of established science.

Physicians should develop much tolerance and sympathy for patients with such complaints. Their troubles should be heard with an open mind. They should be allowed to talk—catharsis or release by expression. History of the patient's life from early childhood to the present must be recorded painstakingly without the usual haste of present day technic. However, familiarity with the technic leads the ingenious physician to many short cuts in procedure. These short cuts may arouse resentment and antagonism unless used with finesse. The physician should always be on his guard not to offend the patient.

Nothing is as private as the emotional life of the patient. He will fence with the physician and try to mislead for the same reasons that prevent him from admitting the real facts to his consciousness. He may relate dreams that are camouflaged as the reason for his symptoms. The physician must gain the confidence of the patient. Once this has been established, the task becomes easier and the resistance less. A thorough clinical and laboratory investigation should always precede the evaluation of the emotional status for two reasons: 1. The significance of symptoms must not be neglected. 2. When the established methods of investigations have failed to yield a satisfactory explanation, the physician's own assurance will be apparent to the patient; his analysis of the mechanism concerned will carry more weight and prepare the patient to accept the physician's advice. If the physician feels that the emotional factors are too deep seated and too complicated, he should recommend that the patient have psychiatric help. The "brow beating" psychiatry of the past is not the method of choice. The patient must be referred to a psychiatrist with insight into modern technics and keenly aware of the sensitivities resulting from emotional factors. The great difficulty arises in convincing the patient of the necessity for this help, because he does not want to feel that there is something wrong with his mind. As experience increases, the physician will find that the mere suggestion creates a resentment, and if the issue is not forced the patient's own desire to seek this help at a later date prevails. The art of medicine in not overtreating the patient applies here equally in not trying to persuade him to do something against his will. Once the physician is convinced of the rationale of this approach, there must be no retreat or the patient will have conquered the physician just as he has repressed or suppressed his own emotional factors.

The psychosomatic approach to disease is no easy road to clinical success. The physician will discover that it requires much study and long practice to acquire competence in this technic.

This discussion will be centered on the gastrointestinal tract, and even here treatment can only be general. I shall also elaborate on my observations of fatigue as seen in patients with psychosomatic disturbances.

The gastrointestinal tract affords a fertile field for such investigation. The abundant clinical material, the frequency of complaints relative to the digestive organs, laboratory study and roentgenologic control provide a foundation on which to build. That the digestive tract should be a seat of altered emotional response is best explained anatomically on the basis of its abundant afferent and efferent nerve supply. The ease of transmission of emotional stimuli from the hypothalamic region to the digestive organs is recognized. Furthermore, no other vital function plays such an important

role in the emotional life of the individual from early life as does eating. The relief from physical discomfort that the infant experiences while eating and the satisfaction of hunger becomes deeply ingrained in the child, being associated with a feeling of well-being and security. In addition, feeding is associated with a feeling of being loved. To a child, feeding and love become inseparable. This oral-receptive manifestation in early infancy is a natural emotional state of the child. In later life it must be suppressed, because it is not harmonious with independent adult life. The repressed oral trends may produce disturbed function leading to changes in the physiologic equilibrium. The recognition of this physiologic imbalance affords the physician an opportunity to explore the symptom complexes of patients and develop adequate and rational therapy. No one is justified in advising the therapy here outlined unless all known organic disease has been eliminated: infectious, parasitic, toxic, neoplastic and even metabolic disturbances of nonemotional origin. Serious organic changes may be masked by neuropsychiatric complaints. Keen clinical judgment should not be discarded because of a new or unestablished panacea. Physicians now recognize that a large percentage of gastrointestinal complaints are due to disturbed function having its origin for the most part in the emotional system. Gastritis, hypertrophic and even atrophic, may thus be classified. The irritability of the gastric mucosa makes it intolerant to food, and symptoms referable to this intolerance are frequently discerned. The same may be true of the duodenum, be the symptoms those of duodenitis, duodenal ulcer or even duodenal stasis.

Dyskinesia of the biliary tract without other abdominal reflex causes may and probably does have its origin in the parasympathetic nervous system. The so-called "stasis cholecystitis" which occurs in hypomotility leads to the formation of gallstones which in turn lead to trauma of the mucous lining, which may be secondarily infected and result in inflammatory disease. "Stasis cholecystitis" may have its origin in disturbed function resulting from altered emotional stimuli reaching the biliary tract.

The disturbances of the small intestine, which may manifest themselves by rumbling and gurgling, colicky and severe cramplike pains, gaseous disturbance, segmental spasm and rapid motility, have been seen in emotionally disturbed patients. Some of the vitamin imbalances, the iron deficiency anemias and disturbed protein and electrolyte balance may be due to the rapid emptying of the small intestine. This increased motility leaves too little time for complete digestion, absorption and utilization of the dietary intake. Hypothetically many of the deficiency diseases have their origin in this mechanism. The disturbed small bowel gives to the colon partially and incompletely digested food which later alters the physiology of the colon. The colon is compelled to do what it normally should not; the results of this disturbed function may be pain, cramps, diarrhea and even constipation. The colon itself may be the receptor of these altered emotional stimuli. Colitis, often used by the physician as an escape diagnosis, is probably the result of the same mechanism. In the majority of cases pathologic changes cannot be found to explain the symptom complex. Even ulcerative colitis has in many cases associated emotional factors. When psychiatric treatment is given in addition to the medical regimen, improvement is frequently observed.

The problem of duodenal ulcer becomes intensely interesting when studied from this point of view. If psychodynamic factors play a role in the life cycle of ulcer, then the time honored method of treatment may be improved. If the hyperacidity is due to some emotional stimulus, prevention of these stimuli from reaching the duodenal and gastric mucosa is more important than the neutralization of the acidity. However, the hyperirritable gastric glands may be more susceptible to hormonal factors from the small intestine, and hyperacidity may result from this phase of gastric secretion. Therefore, until the irritability of the acid cells is decreased, some neutralization may be necessary to buffer this type of increased acidity. The medical regimen for these patients consists in giving aluminum salts or other neutralizing agents a half hour after the three main meals and atropine sulfate in doses of $\frac{1}{100}$ to $\frac{1}{200}$ grain (0.65 to 0.3 mg.) three times a day at meals and at bedtime. In addition, small doses of phenobarbital at meals and at bedtime in doses of $\frac{1}{4}$ to 1 grain (0.016 to 0.065 Gm.), depending on the therapeutic need. The following diet is suggested:

• Avoid:

Coffee, tea, alcohol in all forms, tobacco.
Fried foods, oils, greasy foods, e. g. sardines, salad dressing.
Raw fruits and vegetables.
Whole grain cereal and breads.
Spices and condiments, e. g. mustard, pepper.
Meat, including poultry; meat and meat stock soups.
Sugar, pie, candy, cake, jelly, syrup, honey.

May have items listed—nothing else:

Butter as desired.
Five minute enriched cream of wheat, strained oatmeal and Pettijohns; rice, noodles, macaroni plainly cooked, cornmeal, farina.
Enriched white bread toasted, unsalted white crackers, zwieback, holland rusk, melba toast.
Vegetable milk soups made with puréed vegetables alone; no meat or meat stock to be used.
Lean fresh water fish, e. g. whitefish, perch, trout, bass. To be broiled or boiled alone.
Two eggs daily, either soft boiled or poached.
Cottage and cream cheese in very small portions.
All vegetables to be thoroughly cooked and puréed (as baby foods). Avoid all those with tough fibers and seeds.
Stewed fruit, e. g. prunes, must be puréed. Canned peaches, pears, apricots may be taken whole. All other fruit must be puréed. Juice of strained orange or grapefruit juice daily.
Avoid all syrup of the canned fruit.
Mashed, baked or boiled potatoes are permissible.
Baked custard, rice and tapioca pudding (no raisins), vanilla blanc mange, plain fruit gelatins.
Milk, buttermilk, unsweetened cocoa, small amounts of cream
Only salt to be used in moderate portions.

A sample menu is given in table 1.

The patient with uncomplicated duodenal ulcer responds rapidly to this regimen and is free from symptoms in a relatively short time. Night emptying of the stomach is unnecessary. Complete neutralization of the gastric acidity is not indicated, and many an ulcer will heal promptly under this management. While this management is here given in an abbreviated form, any physician familiar with management of cases of ulcer can fill in the necessary details.

The role played by psychodynamic factors in the life cycle of many patients with ulcer of the duodenum has been well substantiated in recent years. Today it is known that permanent cure of a peptic ulcer patient cannot be secured where the unconscious emotional factors are significant in the clinical picture unless these emotional factors are carefully evaluated and properly

eradicated. The recurrence of peptic ulcer can often be ascribed to the failure of the physician to take these factors at face value. Symptomatic relief due to any medical or surgical procedure is not enough. However, psychoanalytic or psychologic study, be it brief or prolonged, must always be combined with adequate medical control. Only through the pooling of all efforts, somatic and psychologic, can we hope to bring about a permanent cure of these conditions. It is important in this connection not to make unwarranted generalizations. For example, gastric ulcer frequently presents an entirely different therapeutic problem. Carcinomatous ulcer or even the remote malignant transformation of a benign to a malignant ulcer is all too frequent to warrant procrastination. Not even the most competent internist, surgeon, pathologist, roentgenologist or, I might add, gastroscopist can differentiate between a benign and a malignant ulcer in questionable cases. The final diagnosis must rest on the microscopic evidence. Therefore I plead for a great deal of care and circumspection in the conservative care of a chronic gastric ulcer. Until reliable differentiation between benign and malignant ulcer can be made, the surgical approach is preferable to any conservative treatment, medical or psychotherapeutic. The simple, early,

physiology, the prevention of reflex phenomena due to stimulation of various foods, the adequate vitamin and mineral contents and finally rapid return to near normal of body metabolism.

2. If altered emotional stimuli may result from the cortical influence on the midbrain, the medication should be directed at either the eradication or the removal of this influence.

3. If stimulation reaching the gastrointestinal tract by way of the parasympathetic system produces pathologic physiology, therapy should be directed at the site of innervation of these nerves to prevent these altered stimuli from producing these changes.

4. Most important is the philosophic concept of complete approach to this syndrome from the psychosomatic point of view. Simply stated, emotional stimuli produce disturbed function; disturbed function ultimately results in pathologic change. The treatment of pathologic change may be medical or surgical, but the fundamental etiologic approach and prevention of recurrence depends on a study and normalization of the emotional status.

FATIGUE

I have previously reported that emotionally disturbed patients may have fatigue which may result in a disturbance of their carbohydrate metabolism. In a further study of a large number of patients I have found that they uniformly gave a so-called "flat curve" when tested by the intravenous glucose tolerance test (chart 1). Furthermore, an additional group of patients who presented not too flat a curve or were relatively hypoglycemic at the end of the two hours after the injection of intravenous glucose also were fatigued. These patients were submitted to a searching clinical and laboratory investigation. In none were there any organic etiologic factors present which could cause their fatigue.

The fatigue had some striking and almost uniform clinical manifestations. It was usually present on awakening, somewhat relieved by breakfast, usually reappeared in the midafternoon and disappeared after a large dinner. Frequently it was associated with severe early morning headache, more prominently associated at times with midafternoon headache (the kind that is often associated with or thought to be due to eyestrain). There was characteristically a pernicious inertia, even to the extent of continuous bed rest. Hypoglycemic attacks of faintness, vertigo, sweating and extreme weakness often were described. Psychologic investigation revealed a lack of zest and enthusiasm in the few patients critically observed by Dr. Franz Alexander. The sugar level observed could be returned to near normal when the patient was given a dose of atropine sulfate hypodermically, $\frac{1}{50}$ or $\frac{1}{75}$ grain (1.3 or 1 mg.) and the intravenous glucose tolerance test repeated under identical conditions as initially undertaken in the first test (chart 2).

INTRAVENOUS GLUCOSE TOLERANCE TEST

The patient presents himself after a twelve hour fast (no morning bath; no water by mouth except oral hygiene) and is weighed. A fasting blood sugar sample is withdrawn. He is then given the intravenous glucose ($\frac{1}{2}$ Gm. per kilogram of body weight of 50 per cent glucose solution and a large syringe, 50 or 100 cc. type). The time for administration is usually two to five minutes, depending on the age of the patient. Samples of blood are then withdrawn at thirty, sixty, ninety and one hundred and twenty minute intervals after the completion of the initial glucose injection. The blood samples are analyzed according to the Folin-Wu method.

TABLE 1.—Sample Menu for Gastrointestinal Complaints

Breakfast	Lunch	Dinner
3 oz. strained orange juice	4 oz. strained cream of vegetable soup	3 oz. tomato juice
$\frac{1}{2}$ cup farina	2 poached eggs on white toast	3 oz. broiled lake trout
3 oz. milk, cream	1 slice white toast	Small baked potato
Unsweetened cocoa	1 pat butter	Purée carrots, 3 oz.
No sugar	Purée spinach	Purée peas, 3 oz.
	Strained applesauce	1 slice white toast
	6 oz. milk	1 pat butter
	No sugar	Canned pear, 3 oz.
		Milk, 6 oz.
		No sugar
Nourishments		
10 a. m.—milk, 6 oz.	3 p. m.—baked custard	9 p. m.—milk, 6 oz.
Bedtime—milk, 6 oz.; buttered toast		
Use saccharin as a substitute for sugar

uncomplicated gastric ulcers that occur frequently in young persons do not necessarily fall into this category. In such cases there is a place for the psychotherapeutic approach under constant medical vigilance.

Duodenal ulcer in its life cycle, its healing and course may be viewed more optimistically; even here when the duodenal ulcer penetrates beneath the mucosa—when it becomes indolent and refractory to medical management—the psychotherapeutic approach does not provide a positive answer. It should not be considered a panacea. Many patients may have to be treated surgically first and only then handed psychotherapeutically to prevent the recurrence or new occurrence of ulcers. The careful, honest evaluation of each case on its merits offers the best possible hope for permanence of cure. One cannot warn too emphatically against making the psychotherapeutic approach a panacea for all patients. Therefore, some medical management should be available which will be helpful not only for the relief of these symptoms but also for placing the patient in a more normal physiologic state, thus preventing untoward emotional stimuli from disturbing the harmonious functioning of the gastrointestinal tract.

SUMMARY

Four basic considerations confront the physician in the medical treatment of these patients:

1. A dietary regimen should be constructed to take into consideration the irritability of the mucous lining of the digestive tract resulting from this pathologic

The results of these values were noted and charted. Attempts were not made to determine the amount of sugar in the urine during the course of this test, because clinical significance did not appear to be attached to such results. Similarly, oral glucose tolerance tests are not of much clinical value because of the uncertainty of the absorption, which frequently leads to false interpretation.

Chart 1.—Intravenous glucose tolerance test: solid line, average normal curve of 30 patients; broken line, average of 55 patients with fatigue.

On the basis of the laboratory data I feel that the fatigue in the patients is due to a relative hypoglycemia, by which I mean that probably these particular individuals have "normal" blood sugar levels which are "hypoglycemic" for their central nervous system.

I do not have physiologic experiments to support my clinical conclusion that this was the only factor in the fatigue. Occasionally the clinician is justified in drawing tentative conclusions from his powers of observation, even though unsupported by colorimetric or other laboratory investigation, particularly when sufficient experimentation has not been done to destroy the validity of the clinical observation. The uniformity of therapeutic results for these patients merits more widespread application of the method and further investigation as to the exact mechanism involved.

In the treatment of these patients diet is important. The diet should be essentially high in protein, moderately high in fat (except in patients with determined pathologic change in the gallbladder, or in those with hyperkinetic dyskinesia of the gallbladder) and relatively high in carbohydrates.

Chart 2.—Intravenous glucose tolerance test: solid line, average curve of 55 patients with fatigue; broken line, average curve of 15 of these patients given 1/50 grain of atropine sulfate hypodermically one-half hour before administration of glucose.

Foods allowed:

Cereals: Any type cooked or dry. Use one serving daily, preferably whole grain cereals.

Breads: Enriched white, whole wheat, light rye; may use melba toast, white crackers, zwieback if desired.

Soups: Vegetable milk soups. Lean meat stock soups.

Meat: Lean meat or fowl. May use crisp boiled bacon at times.

Fish: Lean fresh water fish, e. g. whitefish, perch, trout, bass. To be broiled or boiled. Fresh shrimp and oysters.

Eggs: One daily, either soft, boiled or poached, soft scrambled.

Cheese: Cottage, cream, mild American and mild Swiss in small portions only.

Vegetables: All types cooked and raw are permissible with the exception only of radishes and onions.

Fruits: Fresh, stewed or canned. Use orange or grapefruit at least once daily. Use no syrup of the canned fruit.

Desserts: Baked custard, rice and tapioca pudding, fruit gelatins, cornstarch puddings. Sponge cake, vanilla wafers to be used occasionally, if desired.

Beverages: Milk, buttermilk, tea, coffee, unsweetened breakfast cocoa, cream in small amounts.

Butter: Specified amounts only.

Foods to avoid:

Very fat meat or fish, e. g. sardines, pork, products.

Pie, cake, pastry, candy, sugar, jelly, honey, syrup, alcoholic and carbonated beverages, dried peas and beans, onions, radishes.

A sample menu is given in table 2.

It will be noted that free sugar in any form is omitted. This omission was based on twofold evidence: First, the injection of glucose in normal dogs at a slow rate greatly increases the tolerance of these animals to subsequent more rapid injection; second, the deamination of protein and the formation of carbohydrate go on at a much slower rate in the liver and therefore will give a

TABLE 2.—Sample Menu in Fatigue

more prolonged secretion of dextrose over a long period, and the postdigestive hypoglycemia of these patients will be delayed if necessary to the next intake of food. However, more frequent feedings than the normal three meals a day were used as an additional factor of safety to prevent hypoglycemia from becoming manifest in these patients. This was further amplified by giving a feeding before retiring to prevent hypoglycemic manifestations (possibly associated with the "night" pains of peptic ulcer) between the last regular meal at night and the subsequent breakfast. The patient receives his three main meals, a midmorning feeding, one or two midafternoon feedings and a feeding before he retires at night.

Too much emphasis cannot be placed on the importance of a good wholesome breakfast. The menus outlined will give sufficient weight to this observation. Too many people rush to their occupations without being fortified with needed calories to do the day's work. This is especially true of women, who seem proud that they eat little, particularly at breakfast, only to have their efficiency proportionally reduced by limitations of diet. Absenteeism is noteworthy among those women workers who go regularly without breakfast. One of the most important functions of food is to give the brain an adequate amount of glucose at all times. Therefore it may be assumed that a possible vicious circle may exist. First starvation, then altered brain

physiology, then altered emotional stimuli, more altered carbohydrate metabolism due to these stimuli and finally the escape mechanism of fatigue.

The rapidity of improvement in patients studied and put on this therapeutic regimen was striking. Furthermore, the small group of patients psychiatrically controlled had an improvement in their psychologic status and a definite reduction of the time during which

Chart 3—Intravenous glucose tolerance test *A*, of a patient suffering from fatigue; *B*, one half hour after the administration of 1/50 grain of atropine sulfate hypodermically; *C*, after psychotherapy and medical treatment; *D*, with no medical treatment and no psychotherapy for seven months

psychotherapy was needed. The psychiatrist is now fortified with a more normal metabolism in the patient, and his task is definitely easier.

Furthermore, at the outset it was evident that dietary management alone would not suffice; that drugs which paralyze the parasympathetic nervous system would be needed to insure that these emotional stimuli would not reach the pancreas. Clinical experimental studies have shown that atropine will raise the blood sugar and if continuously given should and probably does maintain a relatively high level of blood sugar at all times. Therefore, to insure complete atropinization, these patients were given atropine three times a day at meals in doses varying from $\frac{1}{75}$ to $\frac{1}{200}$ grain (1 to 0.3 mg.) and at bedtime from $\frac{1}{150}$ to $\frac{1}{200}$ grain (0.4 to 0.3 mg.). If undue dryness or visual disturbance was noted, the dosage was reduced. Furthermore, extreme care was instituted in giving atropine to elderly patients

As the fatigue improves, the dose of atropine is gradually reduced. Some patients for whom atropine has been discontinued have remained without fatigue (charts 3 and 4). The number of patients in this category are too few to justify any conclusions, and the time is too short to warrant any definite statements. Additional therapeutic measures, such as small doses of phenobarbital during the day and at bedtime and small doses of thiamine hydrochloride at each of the three meals, were uniformly given to these patients.

The charts presented indicate curves of a group of these patients who have had the intravenous glucose tolerance test, the improvement in 2 patients studied psychiatrically and the results of the intravenous tolerance curves when atropine is not given.

I have been particularly impressed by the good clinical results, the ability of these patients to lead a more nearly normal existence, the improvement in the emotional state, the return of zest and enthusiasm, the increased efficiency and finally the possibility of helping out semi-invalidated patients.

However, a note of warning must be issued. The disappearance of the fatigue may stimulate overactivity, and elderly patients must be told to engage in only those

Chart 5—Intravenous glucose tolerance test *A*, lowest flat curve of the series; *B*, average of 55 patients; *C*, average of 30 normal patients; *D*, average of 15 patients given 1/50 grain of atropine hypodermically one half hour before administration of glucose.

activities compatible with their age and the status of their cardiovascular system. This treatment should not be considered a "fountain of youth."

CONCLUSIONS

1. Physicians must survey more critically the emotional status of patients.
2. They should approach with tolerance and insight the problems of a patient whose symptoms indicate emotional factors.
3. Gastrointestinal symptoms are in a majority of instances due to disturbed physiology resulting from altered emotional stimuli.

104 South Michigan Avenue

ABSTRACT OF DISCUSSION

COLONEL LEONARD G. ROWNTREE, M. C., A. U. S.: Now that we realize that peptic ulcer may fall into the realm of psychosomatic disease, we are taking a long step forward. The war itself has brought the clinching proof of the importance of emotionalism in many diseases, particularly peptic ulcer and other visceral diseases. The war has wrought havoc with nerves, more perhaps in the early days when men were torn with uncertainty as to what they should do or had to face, probably more before induction than after induction. Their nerves play havoc with their bodies and with their viscera, and particularly with their minds. There are millions of young men on whose bodies, viscera and minds this emotionalism is having some effect, mild or severe. I believe that understanding in this

Chart 4—Intravenous glucose tolerance test *A*, of a patient suffering from fatigue; *B*, one half hour after the administration of 1/75 grain of atropine sulfate hypodermically; *C*, after discontinuance of psychotherapy and medical treatment

because of the precipitation of acute glaucoma, or in those with evident eye disease, for whom atropine was distinctly contraindicated. In only 1 case in over 300 in which atropine was used for the fatigue or other psychosomatic disturbances was an allergy noted to the drug. Recent experience with syntropan indicates that it may have a similar therapeutic application, but up to the present good results have not been as uniform as those seen with the use of atropine.

field is one of the crucial needs for the improvement of medical care. I particularly like Dr. Portis's second conclusion, "that a physician should approach with tolerance and insight the problems of patients whose symptoms indicate emotionalism." Emotionalism is nothing of which to be ashamed. All who are worth while have emotionalism. Fear is nothing of which to be ashamed. If we could bring to the young men of this nation the concept and the fact that fear is normal, that it is a part of a protective mechanism and that so long as it is properly controlled it is beneficial and not anything of which to be ashamed, we would accomplish much. This would do a great deal to help the problem of psychoneurosis. Dr. Portis's insistence on the role of fatigue is also correct. Fatigue is rampant throughout the nation. It is much more rampant among those who are emotional.

DR. HOBART A. REIMANN, Philadelphia: I am in complete agreement with Dr. Portis as to the great importance of considering the patient's emotional status or reaction in relation to the disease or complaints from which he suffers. This, in brief, encompasses the field to which the euphonious fashionable name psychosomatic medicine has been given: the management of certain gastrointestinal disturbances as outlined by Dr. Portis with psychotherapy, diet and medication is indeed the treatment of choice for the conditions mentioned. But one must attempt to differentiate whether the emotional disturbance is the apparent direct cause of organic disease, as it may be in peptic ulcer or ulcerative colitis, or whether the organic disease is primary and merely complicates, aggravates or incites emotional disturbance. Dr. Portis's treatment is, of course, useful in either circumstance. Besides, the recognition of underlying difficulties, if they are psychic, will serve to prevent many unnecessary surgical operations. It is not clear whether the fatigue disturbs the carbohydrate metabolism or is caused by hypoglycemia. It is so to confuse cause with effect. Atropine seems to be helpful, as stated, but I suspect that the type of patient discussed could be included under the term vagotonia in the sense used by Eppinger and Hess. If this is the case, hypoglycemia is usually only one of many other evidences of imbalance all of which perhaps require management. It reminds me of a case I often cite for discussion. A man of 54 was a painter with a multitude of complaints. He had persistently subnormal temperature, a bradycardia of 50, a blood pressure of 90/60, and a basal metabolic rate of minus 20. He was treated by various physicians in turn for lead poisoning because he was a painter, for bradycardia, for hypotension and for hypothyroidism, when in fact each of the measurable abnormalities was part and parcel of his general makeup. Furthermore, the type of patient under discussion may be relieved of various complaints referable to one system only to have them shift to another, so that these patients should not be referred particularly to gastroenterologists, cardiologists and other specialists according to their predominant symptoms. There is evidence that shift of this type has occurred *en masse*. According to reports, peptic ulcer is of great importance in the Army at present, so much so that in this war as compared with the last "soldier's stomach" seems to have replaced "soldier's heart" in frequency or in fashion.

DR. SIDNEY A. PORTIS, Chicago: I would like to reemphasize that when we exclude carcinoma, neoplastic disease, parasitic and bacterial infections, metabolic disease and intoxications we must have a logical explanation for the symptoms of which the patient complains. The medical schools are noticeably lax in their discussion of pathologic physiology as it relates to man, and for the most part physiology is taught from observations on dogs. It is this approach to the problem which I have tried to emphasize. I am not willing to admit that all peptic ulcer is of psychosomatic origin, but I think the greater percentage of these ulcers are associated with a problem due to emotional disturbances. No one needs a better example than the occurrence of a large number of peptic ulcers in our 18, 19 and 20 year old soldiers. This group offers excellent opportunities for

studying the incidence of ulcers associated with emotional disturbances. Certainly no one could say that these soldiers have been exposed to the ravages of life, and one can only conclude that peptic ulcer is an organ language for emotional disturbance. We as physicians must be fully prepared to solve these postwar medical problems. The army has to be prepared with enough insight to handle this situation, or the veterans' bill following World War II will be stupendous. Dr. Reimann raised the question whether or not slight deviations from normal in blood sugar could cause the symptoms which were outlined. It seems to me that we shall have to change our ideas on the clinical significance of blood sugar levels. Formerly we would talk only about hypoglycemia in terms of 30 or 40 mg. per hundred cubic centimeters. This work has shown that deviations of 5 or 10 or 15 mg. per hundred cubic centimeters make the difference between fatigue and normal energy. The rapidity of response of the patients to the management outlined was so striking that I think this conclusion justified. Finally we, as physicians, must be exceedingly tolerant, gain insight into the problems of the patient and help him over that hump over which he has no conscious control, namely his disturbed emotional system.

COMBINED PENICILLIN AND SULFONAMIDE THERAPY

IN THE TREATMENT OF PNEUMOCOCCIC
MENINGITIS

ANTONIO J. WARING JR., M.D.

AND

MARGARET H. D. SMITH, M.D.

BALTIMORE

Before the advent of chemotherapy, pneumococcic meningitis was an almost invariably fatal disease. Recoveries were rare. The mortality was greater than 99 per cent. In 1927 a review of the literature revealed only 150 recoveries.¹ With the appearance of the sulfonamides the mortality rate for the first time seemed less forbidding, varying, according to different authors, from 31 per cent to 80 per cent.²

Since 1937 the use of type specific antipneumococcic rabbit serum in conjunction with sulfonamide therapy (sulfapyridine, sulfathiazole, sulfadiazine, sulfapyrazine and sulfamerazine) has come into fashion. There again reports of the comparative advantages of combined serum and sulfonamide therapy as opposed to sulfonamides alone are somewhat equivocal. Certainly the advantages of combined therapy are not particularly striking, and in many cases the overzealous use of serum may be actually deleterious. The use of intrathecal serum, for example, is probably ill advised, as is the pushing of intravenous serum to high levels after an adequate reaction is obtained with the patient's own serum. In most instances it is noted that the mortality seems somewhat lower in the group of patients given combined therapy, and therefore the use of serum with sulfonamide therapy is probably justified if not carried to excess.

From the Department of Pediatrics, Johns Hopkins University, the Harriet Lane Home, Johns Hopkins Hospital and Sydenham Hospital, Baltimore City Health Department.

1. Goldstein, H. Z., and Goldstein, H. L.: Review of Literature on Pneumococcus Meningitis, *Internat. Clin.* 2:155 (Sept.) 1927.
2. Steele, C. W., and Gutlieb, J.: Treatment of Pneumococcus Meningitis with Sulfanilamide and Sulfapyridine: A Statistical Study of Reported Cases in Which Chemotherapy Was Used, *Wash. J. Med.* 42:101 (Spec. Antipneumococcus Serum, Arch. Int. Med. 64:211 (Nov.) 1934) Hodges, Gubbel and Barrett: *Hodges, Smith and Jones*.

Since this paper represents the most recent experience at the Harriet Lane Home and Sydenham Hospital, Baltimore, it is felt worth while to recapitulate the past results in these clinics in the treatment of pneumococcic meningitis, most of which have been published. Between 1930 and 1936, 29 cases were seen at Sydenham. No therapy other than supportive was used. The mortality was 100 per cent. The comparable series in the Harriet Lane Home (August 1912 to January 1937) consisted of 150 cases. These received the usual treatment of stimulants, transfusions and spinal drainage. There was not a single recovery in this entire series.

From December 1936 to October 1938, 17 patients at Sydenham Hospital were treated with sulfanilamide with 1 recovery. The experience at the Harriet Lane Home was similar: 8 patients were treated with 1 recovery, and that patient developed a severe myelitis with permanent damage. In October 1938 sulfapyridine and its sodium salt became available. In 1939 Hodes, Gimbel and Burnett³ reported a series of 17 cases treated with sulfapyridine with recovery of 8 patients. Since then 43 additional cases (Sydenham Hospital and the Harriet Lane Home) have been reported by one of us.⁴ Therapy consisted both of sulfonamide alone (sulfapyridine, sulfadiazine and sulfathiazole) and of serum and sulfonamide combined. Sulfonamide levels of 8.0 to 12.0 mg. per hundred cubic centimeters were obtained, and serum was given intra-

TABLE 1.—Recoveries by Ages

	Number of Cases	Recovered	Percentage Recovered
Under 2 years.....	32	7	22
Over 2 years.....	28	18	64
Total.....	60	25	42

venously until the patient's serum produced a definite capsular swelling with the patient's own pneumococcus in a dilution of 1:5. The results of experience with pneumococcic meningitis in these clinics are summarized in table 1.

Thus there is striking difference in recovery rate according to the age of the patient. Only 22 per cent of those under 2 years of age recovered, in contrast to 64 per cent of those over 2.

Between January 1943 and November 1943, when the present series of 12 consecutive cases started, no single therapeutic regimen was followed. Some patients were treated with sulfonamide and serum; others, since February 1943, have been treated with penicillin alone. It is difficult to evaluate the results in this group. In the Harriet Lane Home 10 cases were treated in this interval with only 3 survivals. The survivals were all of children treated with sulfonamide and serum. The experience at Sydenham Hospital was similar. Penicillin alone seemed capable of curing the disease only in a small percentage of cases. In other cases it was our impression that it served to check the course of the disease for a space of time but was unable to arrest it completely despite vigorous intrathecal and intramuscular therapy. Recently 21 cases of pneumococcic meningitis treated with penicillin alone were reported to the National Research Council;

of these 21 patients, only 7 recovered. On the other hand, several instances of recovery have been reported following combined sulfonamide and penicillin therapy.⁵

At the time the present series started, we hoped to obtain a clear evaluation of the role of penicillin in the treatment of pneumococcic meningitis. During November 1943 we had in the wards in the Harriet Lane Home a 5 months old Negro infant who died after a forty-four day illness. The patient had received penicillin in high doses intrathecally and intramuscularly for two weeks. Spinal fluid cultures became negative early in the course, but, because of persistent fever and leukocytosis, penicillin was continued. It was later found that the child, having recovered from the pneumococcic infection, had developed an Aerobacter aerogenes meningitis secondary to a cellulitis of the back, and the child died despite sulfadiazine therapy. Autopsy revealed a chronic basilar meningitis and obstruction of the forams of Luschka and Magendie with pronounced hydrocephalus. In retrospect we should probably have discontinued intrathecal penicillin on the seventh or eighth day. The infection was obviously carried intrathecally by a lumbar puncture through the area of cellulitis.

With this result still fresh in mind, we were confronted with 3 cases of pneumococcic meningitis simultaneously in early January. Patient 1 had been in the ward since mid-November and patient 2 since the end of December. Patient 3 was a new arrival and had been under treatment for five days. Our policy at that time was to treat the disease first with a course of penicillin intrathecally and intramuscularly in essentially the doses about to be outlined. After a seven to ten day trial, if the result seemed discouraging, we proposed to change from penicillin to combined use of sulfonamide and serum. Patient 1 was a 4 months old infant who had been treated for six days with penicillin without results. Penicillin was discontinued and the child was started on sulfapyrazine and serum combined. This form of therapy was used for almost four weeks. During the greater part of the time the child seemed neither better nor worse, but spinal fluid cultures remained persistently positive. Suddenly, in the middle of her fifth hospital week, the patient's condition began to deteriorate rapidly; the temperature rose, the child became stuporous and developed convulsions. At this point the blood sulfapyrazine level was 14.0 mg. per hundred cubic centimeters and the patient's serum showed a positive quellung reaction with its own pneumococcus in a dilution of 1:8. It was decided to try a last course of penicillin before abandoning therapy. The child showed an immediate response; the temperature fell, the clinical appearance improved rapidly and the spinal fluid cultures, which had been persistently positive for five weeks, became negative in twenty-four hours and remained so throughout the course. The convalescence was uneventful with no residual damage except for a spastic monoplegia of one arm.

The likeliest explanation seemed to be that for a period of forty-eight hours at least the child was getting intensive combined therapy with a high sulfonamide level, good quellung reaction and adequate penicillin therapy. At this time patient 2, a 15 months

S.: Paper read before the Society of American Bacteriologists, New York City in May 1944.

old white boy, had been on intensive penicillin therapy for almost fourteen days and his condition had suddenly grown worse, the temperature had risen, spinal fluid cultures were positive and the child was becoming increasingly drowsy. At the same time patient 3 had been on penicillin for a period of five days, the tem-

time. Subsequently 1.0 Gm. every four hours is given. Blood levels are determined daily, and the dosage is manipulated in such a manner as to assure the maintenance of a blood concentration between 6.0 and 12.0 mg. per hundred cubic centimeters. Actually, levels over 4.0 mg. per hundred cubic centimeters are probably effective, and it has been our own experience that no advantage is achieved by obtaining levels higher than 12.0 mg. per hundred cubic centimeters. The only drug reactions encountered were both in adults and consisted of drug fever.

Penicillin Therapy.—Intramuscular and intrathecal penicillin is started as soon as the diagnosis is established. There is no regular dosage system for this agent, but the following general rules are observed: Infants and small children receive daily 5,000 to 10,000 Oxford units intrathecally. During the first two to three days of treatment this is given twice daily in doses of 2,500 to 5,000 Oxford units. Thereafter a single intrathecal injection of 2,500 to 5,000 units is given daily. Infants and small children also receive 1,500 to 2,500 units intramuscularly every three hours day and night, a total of 12,000 to 20,000 units daily. Older children and adults receive 10,000 to 20,000 units intrathecally daily and 5,000 to 10,000 units intramuscularly every three hours day and night.

The penicillin is prepared for intrathecal injections by taking up the required dose in 5 cc. of sterile isotonic solution of sodium chloride. A lumbar puncture needle is inserted into the spinal canal and approximately 5 cc. of spinal fluid allowed to drip out into the sterile container. The penicillin is then slowly injected by

Chart 1.—Results of treatment of a 4 months old white girl with meningitis (pneumococcus type VI) showing prompt response to combined penicillin and sulfonamide therapy after failure of penicillin alone and combined sulfonamide and type specific serum.

perature was remaining high, cultures were positive and the child was still drowsy. It was felt that penicillin alone was failing to cure those cases. Accordingly, sulfonamide and penicillin were used simultaneously.⁶ Spinal fluid cultures of patient 3 became negative, and, except for a period of unexplained fever, recovery was uneventful. Combined therapy of patient 2 was halted prematurely and a cellulitis of the back developed. The meningitis recurred, but the patient recovered when combined therapy was reinstituted.

Charts 3, 4 and 5 demonstrate the effectiveness of combined penicillin and sulfonamide therapy when instituted early in the course of the disease.

TREATMENT

We now proceed as follows as soon as the diagnosis of pneumococcal meningitis is established:

We do not feel that any one sulfonamide presents particular advantages over the others; sulfadiazine and sulfapyrazine are usually used for our patients. The initial dose in most instances is given intravenously in the form of the sodium salt, which for children is 0.05 Gm. of the sodium salt per kilogram of body weight, freshly made up in a 5 per cent solution with distilled water. At the same time the patient receives 0.1 Gm. per kilogram of body weight by mouth or, if unconscious, by stomach tube. From then on approximately 0.2 Gm. per kilogram of body weight is given in six divided doses during each twenty-four hour period. Adults receive initially 3.0 Gm. intravenously and 2.0 to 4.0 Gm. by mouth at the same

Chart 2.—Results of treatment of a 15 months old white boy with meningitis (pneumococcus type XVI) which failed to respond to adequate penicillin therapy but apparently responded to combined penicillin and sulfonamide therapy. Spinal fluid cultures again became positive when penicillin was discontinued prematurely, but when combined therapy was reinstituted there was a prompt response with recovery.

syringe into the spinal canal. Particular care is taken to avoid going into the same interspace twice in succession; the three upper lumbar spaces are used in rotation. Whenever possible, treatments are performed by the same individual; rigorous sterile technic is always employed, the operator preferably wearing rubber gloves.

6. The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

Ill effects were few. One patient, who had had numerous lumbar punctures before combined therapy was instituted, developed a cellulitis of the back. The adult patients complained in several instances of headache and nausea following intrathecal injections. This type of reaction had previously been noted by Rammelkamp and Keefer.⁷ Our patients did not show definite pleocytosis. One complication should be mentioned, however, which may have been secondary to intrathecal penicillin. A 2 months old infant (patient 10) received 20,000 units of penicillin intrathecally in a single injection. The child had been sick only twenty-four hours at the time treatment was begun. She had a negative spinal fluid culture after twenty-four hours of treatment and otherwise underwent an uneventful recovery. Unfortunately she developed optic atrophy and was discharged totally blind. This occurrence may bear no relationship to the intrathecal dose of penicillin, but it should give us pause before injecting unnecessarily large amounts of penicillin into the spinal canal.

The general rule which has evolved for the maintenance of combined therapy is that treatment be continued for at least six days following the last positive

the acute phase of the illness has passed. Since we have been using combined therapy the question of mastoidectomy has not arisen.

Other Forms of Treatment.—General supportive measures are used as indicated. Fluids are forced by mouth and gavage. If vomiting is a prominent feature

the fluid complement is maintained through intravenous or subcutaneous routes. In the face of high fever or collapse, continuous intravenous infusion is employed and blood plasma, 10 per cent glucose, 5 per cent glucose and isotonic solutions of sodium chloride are given as indicated.

For infants we use 0.45 per cent in preference to isotonic solution of sodium chloride. If possible, the needle (ranging anywhere from a size 25 to

Chart 4.—Results of early treatment of a 7 year old white girl with meningitis (pneumococcus type III), showing prompt response to combined penicillin and sulfonamide therapy.

19) is taped into a scalp, wrist, arm or ankle vein. In the case of infants, if no such vein is available, a cannula is tied into the saphenous vein at the ankle. We have found that a cut off lumbar puncture needle (size 19 or 20) serves very well. When fluids are discontinued at any time, the stylet, which is kept sterile at the bedside, may be inserted. The needle and vein remain patent for periods of six to eight hours, and fluids may be resumed at will. The only necessary procedure before the resumption of fluids is

Chart 3.—Results of treatment of a 16 months old white girl with meningitis (pneumococcus type XII) whose treatment was instituted early in the course of the disease, showing prompt response to combined penicillin and sulfonamide therapy.

spinal fluid culture. After this period has elapsed penicillin is withdrawn, but the sulfonamide is continued for an additional seven to fourteen days. After the sulfonamide has been discontinued the patient is kept in the hospital for at least a week with no specific treatment at all.

Serum.—Type specific antipneumococcal rabbit serum was employed in 4 of our 12 cases. The methods used were essentially those outlined by Hodes, Smith and Ickes.⁴ It was used in cases early in our series when we were unsure of our scheme of treatment and any minor reversal seemed an indication for its use. In the light of subsequent experience we feel that, in all probability, it contributed little to the ultimate recovery of our patients. Intravenous serum should be kept in mind, however, as an additional procedure in cases of relapse despite adequate combined therapy.

Operative Procedures.—Unless there is obvious need for surgical drainage of a sinus or a mastoid, it is felt that these procedures should be avoided. Myringotomy is performed freely as indicated. In any event it is our present policy to defer any surgical procedure until

Chart 5.—Results of early treatment of a 40 year old white man with meningitis (pneumococcus type III), showing prompt response to combined sulfonamide and penicillin therapy.

that 10 to 15 cc. of isotonic solution of sodium chloride be forced through the cannula with a syringe. The use of the cannula and stylet has many advantages with small infants and those having precarious circulations.

Sedation is often necessary. We use paraldehyde, either by gavage or by intramuscular injection, and avoid the use of the barbiturates, codeine and morphine.

7. Rammelkamp, C. H., and Keefer, C. S.: Absorption, Excretion and Toxicity of Penicillin Administered by Intrathecal Injection. *Am. J. M. Sc.* 205: 342 (March) 1943.

RESULTS

In 12 consecutive cases of pneumococcic meningitis combined use of sulfonamide and penicillin was employed. Eight of the patients were infants ranging from 2 to 16 months of age. One was a child of 7 years. The remaining 3 were adults. The majority of the cases were seen early in the disease, 9 within the first forty-eight hours, 3 within the first seventy-two hours.

Foci of infection other than the meninges were common, and in all cases the same pneumococcus found in the spinal fluid was present elsewhere in the body. In 6 instances the meningeal signs were either accom-

panied by the pneumococcus was isolated from the nasopharynx.

In all cases the pneumococcus was cultured from the spinal fluid. In 7 cases the same organism was found in the blood stream.

The spinal fluid was cultured at the time of each intrathecal treatment, and spinal fluid sugar and protein determinations were made at regular intervals. These values were of some aid in following the course of the disease, but the correlation between the clinical and bacteriologic progress and the protein and sugar levels was variable.

TABLE 2.—Results in 12 Cases of Pneumococcic Meningitis Treated with Combined Penicillin and Sulfonamide

Case No.	Name, Age, Color, Sex	Condition on Admission	Spinal Fluid Findings	Previous Therapy	Combined Therapy	Spinal Fluid Sterile (Days After Combined Therapy Begun)	Duration of Combined Therapy	Outcome
1	J. A. H., 4 mo. W. ♀	Stuporous; convulsions; T. 39.8 C.	Pneumococcus VII, 800 polys	Sulfathiazole 3 days; penicillin 6 days; sulfadiazine and serum 27 days	Sulfadiazine; penicillin 5,000 units intrathecally q. d. and 1,500 units intramuscularly q. 2 h.	2	2 days	Recovered (spastic paralysis, right arm)
2	J. McM., 15 mo. W. ♂	Ophthalmitis; pneumonia; otitis; T. 38.4 C.; B. P. 30/0	Pneumococcus XVI, 2,150 polys	Penicillin 6,000 units intrathecally q. d. and 2,500 units intramuscularly q. 3 h. for 14 days	Sulfapyrazine; penicillin 6,000 to 10,000 units intrathecally q. d. and type specific rabbit serum 100,000 units	12	1st course 8 days, 2d course 11 days	Recovered (partial paralysis; total deafness)
3	B. L., 8 mo. W. ♂	Stuporous; convulsions; otitis; T. 40.0 C.	Pneumococcus XIX, 8,900 polys	Penicillin 6,000 units intrathecally q. d. and 2,000 units intramuscularly q. 3 h. for 5 days	Sulfapyrazine; penicillin 6,000 units intrathecally q. d. and 2,500 units intramuscularly q. 3 h.; type specific rabbit serum 90,000 units	3	8 days	Recovered
4	R. M. S., 16 mo. W. ♀	Irritable; drowsy; T. 39.0 C.	Pneumococcus XII, 415 polys	0	Sulfadiazine; penicillin 10,000 units intrathecally q. d. and 2,000 units intramuscularly q. 3 h.	2	8 days	Recovered
5	S. W., 52 yr. C. ♂	Comatose; disoriented; T. 39.8 C.	Pneumococcus XXXVI, 3,750 polys	0	Sulfadiazine intrathecally	2	4 days	Recovered
6	N. S., 7 yr. W. ♀	Moderately ill; otitis media; T. 40.0 C.	Pneumococcus III, 6,000 polys	Sulfonamide 2 days	Sulfadiazine; penicillin 10,000 units intrathecally b. d. and 10,000 units intramuscularly q. 3 h.	1	8 days	Recovered
7	L. M., 9 mo. C. ♂	Pertussis; pneumonia; convulsions; otitis; T. 41.0 C.	Pneumococcus XIV, 2,000 lymphocytes	Sulfadiazine 2 days	Sulfadiazine, later sulfapyrazine; penicillin 5,000 to 10,000 units intrathecally b. d. and 2,500 to 5,000 units intramuscularly q. 3 h.; type specific rabbit serum 300,000 units	12	18 days	Recovered
8	H. G., 40 yr. W. ♂	Seriously ill; drowsy; otitis; T. 41.0 C.	Pneumococcus I, 650 polys	Sulfonamide 2 weeks (irregularly)	Sulfadiazine; penicillin 5,000 to 10,000 units intrathecally b. d. and 5,000 to 10,000 units intramuscularly q. 3 h.	2	9 days	Recovered
9	R. G., 2 mo. W. ♂	Moribund; petechiae; shock; T. 38.4 C.	Pneumococcus XII, 400 polys	0	Penicillin	Died in less than 24 hours
10	M. D., 3 mo. W. ♀	Moderately ill; purulent conjunctivitis; T. 40.0 C.	Pneumococcus XXIX, 6,000 polys	0	Sulfadiazine, later sulfamerazine; penicillin 5,000 to 20,000 units intrathecally q. d. and 2,500 units intramuscularly q. 3 h.	2	18 days	Recovered* (blindness)
11	M. A., 52 yr. O. ♀	Moderately ill; pneumonia; T. 39.4 C.	Pneumococcus XII, 4,800 polys	Sulfonamide 3 days	Sulfadiazine; penicillin 10,000 units intrathecally q. d. and 5,000 units intramuscularly q. 3 h.	5	11 days	Recovered
12	N. L., 6 mo. C. ♂	Moderately ill; dehydrated; otitis; T. 38.5 C.	Pneumococcus XXXIII, 4,800 polys	0	Sulfadiazine; penicillin 2,500 to 5,000 units intrathecally and 2,500 units intramuscularly q. 3 h.	2	9 days	Recovered

* This patient was treated at the Union Memorial Hospital, and permission to report the case was given us by Dr. D. C. Wharton Smith and his staff.

panied or preceded by purulent otitis media, and the offending pneumococcus was isolated from the ear and nasopharynx. Three cases were complicated by pneumonia at the time of admission. In one patient, a 9 months old Negro boy, the pneumonia itself was a complication of pertussis. In another patient, a 3 months old white girl, the original source of the organism appeared to have been a conjunctivitis. A history of preceding trauma was obtained in only 1 instance, a 52 year old Negro man who had been struck on the head two days prior to admission and had bled from the ear. No fracture of the skull was demonstrable. In 1 case the only infection noted was a pharyngitis,

Previous treatment of one sort or another had been employed in 7 cases. Four patients received sulfonamide for forty-eight to seventy-two hours before combined therapy began. Three patients had received intrathecal and intravenous penicillin in adequate dosage for periods of five, six and fourteen days respectively. One patient had had penicillin for six days and sulfadiazine and serum for twenty-seven days. In all cases, despite previous treatment, the spinal fluid cultures were positive at the beginning of combined therapy.

The average duration of combined treatment was 10.2 days, the shortest being an estimated forty-eight hours, the longest eighteen days. The latter was in

the case of a relapse, however. Spinal fluid cultures became permanently negative in an average of 4.1 days, but the general average is increased by the 2 cases in which relapse occurred and in each of which the spinal fluid became negative on the twelfth day. In 7 cases the spinal fluid culture had become negative by the time the second therapeutic lumbar puncture was performed. Combined therapy was maintained in most instances from five to seven days after the spinal fluid had become negative.

Sulfonamide was usually continued after the penicillin was stopped, but in the 2 patients who developed drug fever the penicillin was continued when the sulfonamide therapy had to be terminated.

Recurrences were observed in 2 cases. In 1 of these (patient 2) therapy was stopped early because of cellulitis of the back. In the other (patient 7) the penicillin dosage was reduced on the third day of treatment. Both patients had a protracted course.

The only death in this series occurred within ten hours of the patient's admission. Patient 9 was a 2 months old white boy who was admitted in collapse, covered with petechiae and breathing in short, spasmodic gasps; the blood pressure was unobtainable. Shortly after admission the child developed acute dilatation of the stomach and began to vomit changed blood. He was treated with gastric lavage, intravenous saline solution, 50 per cent glucose, blood and adrenal cortex extract and also received initial doses of penicillin and sulfadiazine. The blood pressure rose for a while, but the child again went into circulatory collapse and died ten hours after admission.

Thus there were 11 recoveries and 1 death within ten hours of admission. The death occurred too quickly to be a fair test of any form of therapy. Residua, consisting of a spastic monoplegia and bilateral nerve deafness, occurred in 2 cases. In both of these the meningitis had been active for thirty-six days and seventeen days respectively before combined therapy was started. Patient 10 developed optic atrophy. As

Chart 6.—Age incidence of pneumococcal meningitis during the first fourteen years of life: 206 cases (Harriet Lane Home, August 1912-July 1944). First year of life 137 cases, second year 30, third year 10, fourth year 5, fifth year 3, sixth year 2, seventh year 2, eighth year 2, ninth year 2, tenth year 2, eleventh year 5, twelfth year 1, thirteenth year 2 and fourteenth year 1.

mentioned earlier, this may possibly be due to excessive intrathecal dosage of penicillin. In all cases the general performance level seemed unimpaired.

AGE INCIDENCE

As has been pointed out earlier in this paper, the mortality in pneumococcal meningitis is particularly high in infants. In order to determine whether the present 12 cases form a representative group with regard to age, a study was made of the age incidence

of pneumococcal meningitis in the pediatric age group (0-14 years) based on the Harriet Lane Home records over a period of thirty-two years (August 1912 to July 1944). The figures are tabulated in chart 6; we feel, on the basis of this chart, that the 12 cases in our present series represent a fair sampling.

A total of 206 cases are presented. Of these, 137 (66.4 per cent) occurred during the first year of life. Thirty (14.5 per cent) occurred during the second year of life. The remainder were scattered fairly uniformly over the following twelve years. Thus 80.9 per cent of all the cases admitted to Harriet Lane Home fell in the age group in which the mortality has been demonstrated to be 78 per cent with the best of serum and sulfonamide therapy.

When the 167 cases occurring during the first two years of life are broken down into three month intervals, an interesting curve is obtained (chart 7). The incidence is high during the first three months, rises to a peak at about the sixth month of life and then begins to fall off abruptly.

Six cases occurred in very young infants. The youngest was in an infant 5 days old. One occurred at 2 weeks, another at 3 weeks. Three cases occurred at 1 month of age. There were no recoveries in this group.

COMMENT

In the light of the age incidence of pneumococcal meningitis and the difference in mortality according to age group, it will be noted that the present series has a representative age distribution. Eight of our 12 cases fall under 2 years of age. With serum and sulfonamide therapy we could have expected to lose 6 or 7 of these 8 infants. Under penicillin and sulfonamide therapy we lost 1. All 4 older patients recovered. Under the old form of therapy we would have expected to lose 1.

The pneumococcus types isolated from these 12 cases were in most instances different. Type XII was recovered three times. Other than this there was no reduplication of type.

Case 4 was of interest in that the meningitis occurred in a child that had been followed in the Harriet Lane Dispensary as a proved case of toxoplasma encephalitis. There was no other patient with a previous history of central nervous system disease.

The question of mastoidectomy often comes up in the younger age group. Two thirds of our patients are infants, and most have otitis media. We feel that during the first two years of life the mastoid cells are more or less involved in all cases of otitis media. While the mastoids and middle ear may well be the source of the bacteremia or septicemia responsible for the meningeal infection, direct extension from the mastoid is probably rare and usually cannot be demonstrated at postmortem examination. Mastoidectomies were performed in 2 of our cases, but that was before the present

Chart 7.—Age incidence of pneumococcal meningitis during the first twenty-four months of life: 167 cases (Harriet Lane Home, August 1912 to July 1944). 0-3 months 28 cases, 3-6 months 42 cases, 6-9 months 39 cases, 9-12 months 27 cases, 12-15 months 16 cases, 15-18 months 7 cases, 18-21 months 5 cases, 21-24 months 2 cases.

system of combined therapy was begun. We feel that the procedure is rarely justified.

Twelve cases form too short a series for statistical analysis, but our experience suggests that combined use of sulfonamide and penicillin gives results which are not obtained by the use of either agent alone or by the use of combined sulfonamide and serum.

SUMMARY

1. Twelve patients with pneumococcic meningitis were treated with combined sulfonamide and penicillin therapy.⁸

2. Of these 12 patients, 11 recovered and 1 died. Death occurred within ten hours of admission. Three had previously failed to respond to penicillin therapy alone.

3. These results are better than our experience with sulfonamide alone, with sulfonamide and serum combined or with penicillin alone.

4. Two hundred and seven cases of pneumococcic meningitis admitted to Harriet Lane Home (August 1912 to July 1944) were analyzed on the basis of age incidence and the data presented in chart form, demonstrating (a) the high incidence of this infection during the first year of life and (b) the fact that our 12 recent cases represent a fair sampling with regard to age.

5. If combined sulfonamide and penicillin therapy is used, particular pains must be taken to pursue both forms of treatment vigorously as well as simultaneously.⁹

EFFECTS OF TETRYL

MAJOR E. W. PROBST

MEDICAL CORPS, ARMY OF THE UNITED STATES

LIEUTENANT M. H. MUND

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

L. D. LEWIS, B.S., M.T. (ASCP)

DOYLER, N. J.

Since the literature concerning the chemistry and toxic effects of tetryl has been reviewed by other writers, we have intentionally avoided repetition and confined our remarks to the clinical experiences and observations of the medical department of an arsenal with the hope that we shall be of practical assistance to physicians who have patients working in the munitions industry.

Our study of the effects of tetryl was made on a working population of about 800 to 900 employees in the tetryl areas. Although most of the workers were engaged in loading operations, some were doing research work and manufacturing tetryl. To make our study complete we included a very small group that worked in the areas but had no direct contact with tetryl, such as guards, janitors and clerks.

These employees were observed in the work rooms, in the dispensary and during periodic examinations, which in most cases were done monthly and consisted of a complete history, blood count, urinalysis, blood pressure determination according to the Foulger system,¹

physical examination and other tests as indicated. Employees who exhibited dermatitis or complained of eye, nose and throat symptoms or other symptoms were given special attention.

Skin irritation was found to be a common complaint of tetryl workers. Although the incidence of dermatitis was gradually decreasing as the result of control measures, an average of 4 per cent of the tetryl workers were found to have dermatitis. Of all dermatitis cases seen at this arsenal, 62 per cent were caused by tetryl.

Most of the dermatitis cases occurred in the loading areas, probably because these areas employed the most people and most of the loading operations invited spillage and skin contact. Pellet production and tetryl manufacturing were to some extent closed operations and under better control and therefore offered little opportunity for dermatitis except in a very small group of employees who were allergic to tetryl. Only 2 cases of skin irritation were observed among the laboratory and research workers. One case was a problem of allergy, and the other case was that of a chemist who mopped perspiration from his face with a handkerchief he had carried in his work clothes while working in a dusty area. Severe reactions were noticed in several guards who patrolled areas near tetryl buildings. A clerk who handled time cards and shipping tickets from tetryl buildings was treated for tetryl dermatitis of the face but recovered completely only after she was given a job of handling reports from a tetryl free area.

In reviewing 404 cases of tetryl dermatitis we found that, in general, age, sex and color had no influence. It was noticed that most cases occurred in new workers one to two weeks after their introduction to tetryl. Some individuals developed skin irritation in a few moments, while others required several weeks or even months of exposure before a rash appeared.

The face was found to be most frequently affected, particularly in the circumocular region and in the areas of the face containing natural creases and folds, such as the nasolabial folds and the corners of the mouth. The neck was involved in many cases, particularly at the collar line and in the natural creases. Although the extremities were less frequently involved, these cases occurred at points of friction such as the wrists or ankles and extensor surfaces of the forearms. No cases involving the thorax or genital area were observed.

If seen early, the worker usually complained of slight burning or itching of the skin. Examination in these cases revealed nothing. If the person continued to expose himself to tetryl, an erythema developed in a few hours. In some cases the erythema was accompanied by an edema of the lower eyelids (fig. 1). In severe cases the edema involved the upper and lower eyelids and in some cases was so extensive as to distort the facial features beyond recognition. This phenomenon was particularly observed in workers who were so sensitive to tetryl that merely entering a tetryl area precipitated an attack in a short time.

The typical contact dermatitis as a rule progressed to a papulovesicular stage and then became brawny followed by scaling and some discoloration of the skin (fig. 2). This was particularly noticed in cases in which the neck had been affected by tetryl which was present in coat collars, and in cases of wrists and forearms that had been affected by contaminated coat sleeves or work benches. In a few cases secondary infections and an exfoliative dermatitis were superimposed because of the self medication administered by the patient in an

8. Permission to employ penicillin and sulfonamides simultaneously was given by Dr. Chester Keefer, chairman of the Committee on Chemotherapeutics and Other Agents of the National Research Council.

9. Since submitting this manuscript for publication the authors have had the opportunity to treat another patient with penicillin and sulfadiazine combined. The patient was a white boy aged 14 years with meningitis due to pneumococcus type 37; he made a prompt and complete recovery.

¹Foulger, J. H. Medical Control of Industrial Exposure to Toxic Chemicals, *Indust Med* 12: 214 (April) 1943

attempt to hasten recovery. Several cases of acne were found, particularly in young women, which abated after these workers were removed from tetryl exposure. Similar observations were made in several cases in which dermatophytosis developed on the palms and between the fingers.

Fig 1—Erythema accompanied by edema of lower eyelids

Our observations of the staining of the skin and discoloration of the hair from tetryl exposure did not differ from those of other investigators. It was definitely noticed, however, that the degree of staining in most cases was directly proportional to the cleanliness of the worker.

Individuals, in our experience, did not appear to develop any immunity or "hardening" on repeated exposures. In some cases when the person was permitted to return to work while under care for dermatitis the condition became worse and the person became exceedingly uncomfortable and had to be removed from the area. For this reason we pursued a policy of removing all operators from exposure until treatment was completed. By following this system all but a very small group of allergic persons were ultimately returned to their regular jobs.

All cases were treated as individual problems. In general persons mildly affected were treated with 10 per cent boric acid ointment and removed from exposure for several days. Persons more severely affected were sent home and treated with 5 per cent sodium bicarbonate wet dressings followed by boric acid ointment and were returned to their regular job after treatment was completed. Persons with pronounced allergy were not permitted to return to any exposure and persons with very severe allergy were granted releases to obtain a job in a tetryl free environment.

Thirty-five patients were treated with a 5 per cent aqueous solution of sodium thiosulfate. These patients were given 20 cc. intravenously each day for two or more days. In less than 50 per cent of these cases, itching and burning stopped and the rash began to fade. However, 10 cases failed to respond to this treatment. At this time of writing we have come to no conclusions, as this treatment is still under trial.

In evaluating the effect of tetryl on the eyes, ears, nose and throat as seen in over 500 employees in the course of one year's investigation at this arsenal, no

systemic reactions can be said to have occurred. Most of our complaints were exaggerated because of a wholesale fear of "tetryl or powder poisoning." Apparently in this arsenal "powder poisoning" phobia is part and parcel of fear of trinitrotoluene poisoning. All powder is suspect, but tetryl in particular, because of its early irritative effects, gives us the most complaints. This ungrounded fear of tetryl is unwarranted and should be discouraged by all concerned.

The effect of tetryl on the eyes and adnexa was one of primary chemical irritation, resulting in an erythema of the lids combined with pruritus of the lids. Trauma, rubbing and scratching resulted in lid edema. Some cases showed such pronounced edema, noninflammatory in nature, that allergy must be considered as playing some part. The bulbar and palpebral conjunctivas were not affected despite the often intense erythema and edema of the lids. Injection of the conjunctiva, when present, had been slight and easily explained on the basis of trauma. Those cases exhibiting pronounced conjunctivitis with lacrimation, photophobia, blepharospasm, itching and smarting have been demonstrated to be infectious in nature and merely coincidental with tetryl complaints.

In our study vision has never been affected. No cases of corneal infection or ulceration have been seen, and routine ophthalmoscopy has been negative.

Hearing is unaffected by working in, or exposure to, tetryl powder. In the past year there have been only 15 cases in which complaint was made of impaired hearing, and these were found to be due to cerumen impacted in the canal and to acute otitis media. We have been on the lookout for eighth nerve involvement but have found none.

Fig 2—Typical contact dermatitis.

Headache has not been a prominent symptom among our employees working in tetryl. Our statistics show that in an average of over 500 workers in this material complaints of headache occurred in only 4 per cent of workers coming to the clinic. On routine questioning by laboratory technicians, 21 per cent complained of headache at one time or another, but nothing specific as to the location, severity, times of occurrence or

duration was present. We therefore consider tetryl exposure of no significance in causation of headache.

The nose and throat have been the chief organs affected by tetryl in our eye, ear, nose and throat study. Complaints referable to the nose included all those seen with the ordinary common cold. Subjective symptoms included nasal dryness, burning or sneezing, stuffiness, smarting and anosmia. Added to these were many cases of epistaxis. These symptoms occurred early in the course of employment, usually in the first two weeks, although many employees complain of nasal irritation after only a few hours exposure. The subjective sensations were analogous to those of the common cold, except that the initial stage of dryness and smarting was not succeeded by increased mucous secretion. Objective signs were a dry injected nasal mucosa, with edematous turbinates. The color of the nasal mucosa was a bright scarlet, even in the colored race, except where allergy was present, when the color was slaty gray in the colored race and varied to a pale pink in the white race. In the absence of concomitant infection, no discharge was present. The mucosa remained dry and glairy and even after a week of further exposure did not become moist.

It was of interest to note that subjective complaints were in almost all cases associated with objective nasal pathologic changes in the form of deviations of the nasal septum, chronic hyperplastic rhinitis, nasal polypoidosis and varied forms of allergic rhinitis. It was practically an invariable finding to note that tetryl workers with poor nasal ventilation due to obstruction of septal deviations and enlarged turbinates had complaints early in the course of their work.

Epistaxis was a common finding, occurring in 14 per cent of workers routinely questioned by laboratory workers. It was never alarming or profuse. Its origin was usually at Kiesselbach's area and associated with capillary engorgement. Much of it was due to finger trauma occasioned by the dryness of the mucosa. Occasionally the lower turbinate, anterior border, showed factitious ulcers. Bleeding usually stopped spontaneously, and packing with cotton or gauze was rarely resorted to. The use of a simple nasal constrictor such as 2 per cent ephedrine sulfate drops was usually sufficient to restore nasal comfort and relieve complaints.

Throat symptoms consisted of dryness, cough, smarting and tightness in nervous persons. Objectively the pharynx was dry, glazed and injected. It was a conspicuous finding that most of these employees also showed pathologic change in the form of chronic infection of the tonsils, pharyngeal and lingual, as well as a chronic pharyngitis with lymphoid follicle enlargement.

These findings have led us to conclude that in workers exposed to tetryl for the first time antecedent infection and anatomic abnormalities of the nose and throat were primary agents in the development of symptoms. Many of these workers were advised to seek medical and surgical treatment, and those that did were able to return and work free from symptoms. Those that did not seek treatment were seldom free from symptoms and eventually had to be taken out of tetryl exposure.

The question of allergic sensitivity to tetryl, with regard to the nose and throat, is a moot one. In our opinion some patients did develop a typical nasal allergy on exposure to tetryl, with the result that the nasal tissues remained constantly engorged, an ensuing train of symptoms occurring analogous to those of hay fever.

These patients were never comfortable because of mouth breathing and when forced to wear a mask, as in certain operations with tetryl, were unable to do so with comfort. Removal from all tetryl exposure restored normal nasal function in these cases.

Laryngitis and tracheitis specifically due to tetryl, without other signs of infection, have not been found in tetryl workers here.

As our workers have frequent chest x-ray examinations, before employment as well as on annual physical examination, we have been able to detect any pathologic developments in the lungs. Employees with pulmonary pathologic changes are screened out on preemployment examination and are not permitted to work in toxic operations. Accordingly, we were able to keep a strict check on workers in tetryl but to date have been unable to find any pulmonary conditions attributable to powder.

It is notable that symptoms directly due to tetryl arose early in the course of employment. Those symptoms of the nose and throat which are the worst offenders were seen, almost without exception, in employees with previous pathologic conditions. In the few without obvious pathologic conditions, symptoms ceased spontaneously in one to two weeks, but, in the others, symptoms increased to the point where the worker was useless in tetryl operations, and in some workers apparent neuroses intervened. A few workers who developed a nasal allergy on exposure to tetryl were removed early. Systemic symptoms due to tetryl, initiated through the nose and throat, have not been seen.

In the course of routine periodic examinations of tetryl workers we found anemia (defined as less than 11 Gm. of hemoglobin per hundred cubic centimeters for women, less than 12.5 Gm. for men) in only 4 per cent, and 92 per cent of the anemic persons were women. There is no reason to believe that this exceeded the figure for the population at large.

White blood cell count findings were difficult to interpret. Leukocytosis and leukopenia appeared to be completely unrelated to the type and duration of exposure, symptoms or complaints. About the only conclusion we could draw is that leukopenia occurred about twice as often among colored workers as among white workers, while leukocytosis had about the same occurrence in the two races.

Abnormal blood pressure findings occurred with varying frequency in 18 per cent of tetryl workers. Four per cent was hypertension in workers of an average age of 42 years, compared to an average age of 33 years for all tetryl workers. The remaining 14 per cent consisted of hypotension, low pulse pressure and the like, and the average age was 33, the same as the average for all tetryl workers. We have regarded severe or persistent blood pressure abnormalities as sufficient cause for removal from tetryl exposure.

PREVENTIVE PROGRAM²

With the aid of the management and the safety department, we were able to carry out an effective preventive program, which was divided into several phases.

Preemployment and Periodic Examination.—All workers were given a complete preemployment examination, and those who were found to have a disqualifying history and physical defects were not assigned to any work involving tetryl exposure. Employees were given a physical examination annually, and those who were

2. Probst, E. W., and Lewis, L. D.: An Effective Preventive Medical Program. *Indust. Med.* 13: 43 (Jan.) 1944.

found to have physical defects or a history which contraindicated tetryl exposure were removed from exposure and placed in another job.

Routine laboratory examinations of tetryl workers were done monthly or quarterly, depending on the degree of the exposure and the condition of the worker. Significant or persistent abnormalities of blood count, urinalysis or blood pressure were considered indication for removing the worker from tetryl exposure, although each case was reviewed individually by the industrial medical officer before removal.

Environment.—Periodic inspections of the tetryl areas were conducted, and every effort was made to eliminate or reduce the dust by modifying the operations and installing ventilation and exhaust systems. Skin contact with the tetryl powder and pellets was reduced to a minimum.

Protective Clothing and Personal Hygiene.—All exposed workers were furnished with special powder uniforms, which offered fairly good protection. These uniforms were changed frequently and were laundered at the arsenal. Adequate washing and bathing facilities with sufficient soap and towels were made available. Since protective ointment and respirators were found to be generally unsatisfactory, these items were used only when other methods were inadequate.

Education.—An educational program was established to encourage cleanliness in operations, personal hygiene, safety and better nutrition. This program was accomplished by posters, placards, editorials in the plant newspaper and conferences with individual workers.

Other Measures.—In some dusty areas workers were advised not to use their handkerchiefs and were encouraged to use paper wipes. They were also advised not to bring their lunches or personal belongings into the work rooms.

In case of workers with signs or symptoms referable to tetryl exposure, the health records and the work environment were immediately checked and reviewed before any action was taken. Cases exhibiting any severe reaction were removed immediately from exposure.

CONCLUSIONS

The most common finding in tetryl workers at an arsenal was contact dermatitis. A small percentage of the workers were found to show evidence of sensitivity.

Those individuals who had nose and throat complaints showed preexisting pathologic changes except for a few cases of nasal allergy. No evidence of eye pathologic change due to tetryl was noticed.

Under our methods of control, no evidence of systemic illness developed.

First Hospital in Western Europe.—The first hospital in western Europe was founded in 380 A. D. by Fabiola, a Roman matron of distinguished piety. The exact site of this rather famous hospital is uncertain, but St. Jerome describes it as "a house in the country for the reception of the unhappily sick and infirm persons who were before scattered among the places of public resort; where they would be furnished in a regular way nourishment and those medicines of which they might stand in need." To conform with the growing Christian idea of charity, hospitals began to be founded for special purposes; there were hospitals for the sick alone, for foundlings, for orphans, for the helpless poor, for the aged, and for poor and infirm pilgrims.—*The Hospital in Modern Society*, edited by Arthur C. Bachmeyer and Gerhard Hartman. New York, Commonwealth Fund, 1943.

TREATMENT OF MULTIPLE FURUNCULOSIS WITH PENICILLIN

ROSE COLEMAN, M.D.

AND

WALLACE SAKO, M.D.

NEW ORLEANS

The incidence of furunculosis superimposed on miliary is much increased during the warm summer weather. In the South this condition constitutes a common problem which often proves to be very refractory to treatment. The remarkably rapid response of multiple furunculosis to penicillin therapy we have observed in 6 young children serves as the basis of this communication.

REPORT OF CASES

CASE 1.—R. B., a white boy aged 1 year, was admitted to Charity Hospital on June 19, 1944 with numerous furuncles of one week's duration scattered over the scalp, face, neck, shoulders, chest, back and the left thigh. The patient did not

Fig 1 (case 6).—Front view of infant with multiple furuncles of scalp, face and neck at the beginning of penicillin therapy.

appear to be ill, and the rectal temperature was 100.6 F. The physical findings were normal and the blood serologic reaction and the Mantoux test were negative. Local therapy and sulfadiazine administered orally for seventeen days brought no appreciable improvement in the condition of the skin. On July 7 an initial dose of 20,000 units of penicillin was given intramuscularly followed by 10,000 additional units every three hours until July 13. The patient received a total of 440,000 units. Within twenty-four hours after penicillin treatment was begun distinct improvement in the furuncles was noted and without the aid of any local therapy all of the lesions were healed in four days (July 11) except for a large abscess on the left thigh, which drained spontaneously and healed two days later. The patient was discharged on July 14 completely cured of all skin lesions.

CASE 2.—J. A. L., a white boy aged 7 months, was admitted to Charity Hospital on June 22, 1944 with severe miliary and widespread furunculosis of three weeks' duration involving

From the Department of Pediatrics, Louisiana State University School of Medicine and the Charity Hospital of New Orleans.

the scalp, face, neck and upper portion of the trunk. The remainder of the physical examination was negative. The temperature on admission was 102 F. rectally and fluctuated between 97 and 102 for one week. All the laboratory findings were negative except for a leukocytosis of 26,000. Since local

was given. Within forty-eight hours the furuncles began to regress, and hard papular swellings as well as the small fluctuant furuncles became absorbed and completely disappeared after four days of penicillin treatment. The patient was discharged after six days of hospitalization.

CASE 4.—E. B., a Negro boy aged 3 years, was admitted to the hospital June 21, 1944 for cellulitis of the right leg and numerous furuncles of the scalp, face, neck, chest and extremities. The rectal temperature was 101 F. and the blood culture was negative. An initial intramuscular injection of 10,000 units of penicillin was given followed by an additional 5,000 units every three hours until the patient had received a total of 230,000 units. The temperature returned to normal in twenty-four hours and the cellulitis cleared in forty-eight hours. The furuncles began to regress in twenty-four hours and completely disappeared in seventy-two hours except for two large fluctuant abscesses of the scalp, which were incised and drained and completely healed two days later. The patient was well when discharged on June 29.

CASE 5.—B. J. M., a white girl aged 9 months, was admitted to Charity Hospital on June 13, 1944 with multiple furuncles

Fig. 2 (case 6).—Rear view of patient before treatment

therapy and sulfadiazine given orally for seven days resulted in no improvement, the intramuscular administration of penicillin was started on June 30. The initial dose of 20,000 units was followed by additional injections of 10,000 units every three hours, until the patient had received a total of 460,000 units. No local therapy was used after penicillin was started. All the lesions, several of which were fluctuant, improved in twenty-four hours and had completely disappeared seventy-two hours after the penicillin therapy was started. The patient was discharged on July 14, completely cured.

CASE 3.—M. C., a white girl aged 10 months, developed a heat rash in May 1944. On June 1 examination revealed

Fig. 3 (case 6).—Front view of patient showing disappearance of furuncles after five days of penicillin therapy

multiple furuncles on the scalp, face, neck, chest and back. The blood serologic reaction and the blood culture were negative. Local therapy consisting of frequent baths, saline packs, sulfathiazole ointment and staphylococcus vaccine proved of no avail. The patient was hospitalized on June 12 and penicillin therapy was started, 5,000 units being administered intramuscularly every three hours. A total of 200,000 units of penicillin

Fig. 4 (case 6).—Rear view of patient after treatment

of two weeks' duration and bronchopneumonia. The temperature on admission was 103 F. rectally. The physical examination disclosed numerous furuncles over the entire scalp, neck and upper part of the chest. X-ray examination of the chest revealed bronchopneumonic patches of the right lung.

Treatment consisted of incision and drainage of the larger fluctuant abscesses. On June 14 an initial dose of 10,000 units of penicillin was given intramuscularly followed by 10,000 additional units every three hours. A total of 480,000 units was given. The temperature returned to normal in four days. The furuncles and pustules improved rapidly and were completely healed on June 19. The patient was discharged on June 24 and had suffered no subsequent recurrence of furunculosis when seen on July 11.

CASE 6.—E. M., a Negro girl aged 6 months, was admitted to the hospital on July 13, 1944 with the complaint of multiple "boils" of four weeks' duration. The temperature on admission was 102 F. rectally. The physical examination revealed numerous furuncles, small pustules and papules scattered over the scalp, face, neck and shoulders (figs. 1 and 2). A large fluctuant abscess about 3 by 3 cm. was located in the left occipital region. The remainder of the physical examination was negative. The blood culture and serologic test were both

negative. Culture of pus from the abscesses revealed *Staphylococcus pyogenes aureus*. The patient was started on penicillin on July 14. The initial dose was 10,000 units administered intramuscularly followed by 5,000 units every three hours. The total dose was 230,000 units. The temperature came down to normal in three days. The superficial furuncles cleared up in seventy-two hours and the larger furuncles disappeared in five days. The large fluctuant abscess healed promptly after incision and drainage (figs. 3 and 4).

SUMMARY

The rapid disappearance and cure of multiple furunculosis observed in 6 children under penicillin treatment indicates a result far superior to any previously known therapy for this condition.

Clinical Notes, Suggestions and New Instruments

ALLERGY TO PENICILLIN

LEO H. CRIEP, M.D., PITTSBURGH

Urticarial reactions to penicillin have been described by Lyons¹ as occurring in 12, or 15.7 per cent, of 209 cases treated in army hospitals. Following is the report of a case of penicillin allergy manifested by generalized severe urticaria and studied from the point of view of the possible immunology involved in this reaction:

REPORT OF CASE

A man aged 23 was admitted to the United States Veterans Hospital, Aspinwall, Pa., during March 1944 with a diagnosis of suppurative arthritis of the right hip. This condition started in the summer of 1943 while the patient was in the service and followed an abscess on his left elbow. The abscess was incised. Because it was associated with osteomyelitis, penicillin therapy was begun on Oct. 13, 1943. The patient received 200,000 units daily for a period of fourteen days. Penicillin therapy was resumed on Nov. 6, 1943, and he received 120,000 units daily

TABLE 1.—Results of Direct Skin Tests

	Patient C. H.	Controls			
		1	2	3	4
1. Penicillin conc.....	+++	+++	++	++	++
2. Penicillin 1:10.....	+++	++	+	0	0
3. Penicillin 1:100.....	++	0	0	0	0
4. Saline solution.....	0	0	0	0	0

TABLE 2.—Precipitin Tests with Penicillin

Blood Serum	Penicillin Conc.	Penicillin 1:100
1:10.....	Positive	Positive
1:50.....	Positive	Positive
1:100.....	Positive	Positive
1:1,000.....	Slightly positive	Slightly positive
1:10,000.....	Slightly positive	Slightly positive
1:20,000.....	Slightly positive	Slightly positive

until November 12. Immediately on resumption of this therapy, that is on November 6, and following the administration of the first dose of penicillin in this course of treatment, the patient developed massive generalized urticaria, which persisted until the penicillin therapy was discontinued on November 12. The patient stated that the urticarial reaction would occur almost immediately on his receiving the injection of penicillin, and in the period when the drug was given daily the urticaria was continuous and universal. He presented no family history

of allergy. He stated that he has never had urticaria before. There was no history of hay fever, asthma or any other allergic manifestations.

On his last admission to the hospital the measurements of the legs revealed that there was a shortening of the right leg of approximately 3 cm., this shortening being located above the greater trochanter. Roentgenograms revealed evidence of a suppurative process in the right hip with partial absorption of the articular surface of the head of the femur and the acetabulum; the laboratory work was essentially negative; the urine, blood count and serologic reaction were negative.

SPECIAL INVESTIGATION

The following represents an attempt to study the immune bodies accompanying this reaction:

1. *Direct Skin Tests to Penicillin*.—Direct skin tests (intra-dermal) with penicillin drug solution yielded the results, as compared with controls, given in table 1.

2. *Passive Transfer Tests*.—Presence of Reagins: Passive transfer tests performed with the patient's serum yielded a positive reaction with penicillin in a dilution of 1 to 100. These were done on two substitutes. The controls were negative.

3. *Precipitin Tests with Penicillin*.—Controls were done with normal serum, and these showed no precipitin reaction.

4. *Anaphylactic Antibodies*.—An attempt was made to sensitize passively 2 guinea pigs with the serum of the sensitive patients. The serum was injected intravenously into the animals. Following a period of twelve to twenty-four hours, penicillin solution was administered by the same route. Neither guinea pig showed evidence of anaphylactic shock. It would appear therefore that there were no anaphylactic antibodies to penicillin in the patient's serum.

5. *Comparison with Skin Reaction to Penicillium*.—Direct skin tests on the patient with penicillium extract were negative. This is of interest because Feinberg² recently found that individuals clinically sensitive to penicillium spores did not give a positive reaction to penicillin. It would therefore seem that there is no cross sensitization between penicillin (drug) and penicillium (spore) extract.

COMMENT

The urticarial reaction presented by this patient is obviously one of allergy to penicillin. In view of the fact that little is known about the method of preparation of penicillin, it was not possible to conduct investigations which would indicate whether the drug or culture mediums employed in its preparation might be the offending allergen. However, direct skin tests to corn extract and corn steep were negative. Present evidence indicates, however, that the sensitivity is to penicillin itself. This allergy, in all probability, is not unlike that shown in serum allergy. As is the case with other instances of sensitization to biologic products, such as insulin, posterior pituitary injection and liver extract, the reactions occurred after the resumption of treatment following a period during the course of which the drug was discontinued.³ At this time the urticaria occurred immediately after the first injection of the second series. The same thing occurred some months later when treatment with the drug was reinstituted.

There seems to be evidence of the presence of some immune substances in the serum of this patient, such as reagins and precipitins. This is proved by the positive direct skin test, by the positive passive transfer and the positive precipitin test. Just what role, if any, these antibodies might have in mediating the reaction is not exactly clear.

These findings are of interest because they vary with the statement contained in the report¹ that in the patients who showed an urticarial reaction to penicillin "the course" of the urticaria was "independent of continuance or cessation of treatment." Also that "subsequent courses of penicillin therapy in patients with a history of urticaria during the first treatment period have been uneventful and not associated with recurrent urticaria." None of the patients included in the report quoted showed precipitins or positive skin reactions to penicillin.

1. Lyons, C.: Penicillin Therapy of Surgical Infections in the U. S. Army, *J. A. M. A.* 123: 1007 (Dec. 18) 1943.

SUMMARY

1. A case of acquired sensitivity to penicillin was observed.
2. Penicillin allergy is probably unrelated to sensitivity to *Penicillium* spores.
3. Associated with penicillin allergy, there may be found in the serum of the patient immune bodies (reagins and precipitins), but their exact role in the reaction is not known.
4. This form of allergy represents one analogous to drug or serum allergy.

1004 May Building.

ALLERGIC HEADACHE

AN UNUSUAL CASE OF MILK SENSITIVITY

THERON G. RANDOLPH, M.D., CHICAGO

This case report illustrates many of the pitfalls in the general recognition and specific diagnosis of allergic headache. It is of further interest in view of the severity of symptoms and the pronounced degree of food sensitization existing in the absence of skin tests.

REPORT OF CASE

I. K., a graduate nurse aged 24, developed her initial sick headache at the age of 14, one year after the menarche. Symptoms recurred in 1939 at the age of 17. An allergic investigation at this time revealed a negative past and family history for other evidences of allergic manifestations. Cutaneous tests, including foods, were entirely negative. She was placed on a Rowe No. 1 elimination diet for two periods of ten days each. One headache occurred during this interval. At the time of the diet trials she was subject to a headache every three to four weeks.

In May 1940 the attacks of head pain became more frequent and severe. In the following eighteen months she was hospitalized twenty-five times because of severe attacks with one hundred and ten days' hospitalization. Many attacks did not require hospital admission. During this period she lost approximately one third of her time as a student nurse because of incapacitating headaches.

A typical attack began with a sense of pressure and pain over the right frontal sinus, followed by drooping of the right upper lid and twitching of both upper lids and terminated in a prolonged period of severe throbbing right temporal pain which extended to involve the right ear region. The headaches were associated with pronounced photophobia, dizziness, anorexia, nausea and vomiting. When the head pain was most severe she often lapsed into a state of altered consciousness which lasted from a few minutes to as long as forty-five minutes. At the onset of these periods she temporarily lost motor control, several times falling and injuring herself. These attacks were characterized by varying degrees of stupor from which she could be only partially aroused. She appeared to be oriented but responded with a prolonged reaction time. Apparently perception was normal, but she had some difficulty in enunciating and spoke in a monotone with slurring of syllables. She claimed that during these times she had difficulty to find the words to express her thoughts. There were no convulsions, incontinence, opisthotonos or biting of the tongue.

The headaches varied in length from two hours to ten days. They were associated with and followed by fatigue to the point of utter exhaustion. As the headaches became more frequent, troublesome fatigue persisted between attacks, materially interfering with her efficiency in studying and working. Her fatigue was unrelieved by obtaining the customary amount of rest prescribed for student nurses, nor was it relieved by excessive rest. It occurred whether at work or on vacation. Coincident with the persistent fatigue, her friends noticed that she was less alert than formerly.

Her physical examination was consistently negative between attacks. During attacks she was extremely restless, writhing and clutching her head in her arms with each recurrent pain. There was drooping and slight edema of the right upper eyelid, twitching of both upper lids, a fine nystagnus and tenderness

of the right face and neck region. At the height of the symptoms the pulsations of the right temporal and carotid vessels were stronger than the left. There were no other physical findings.

Blood counts and other routine laboratory data were within normal limits during and between attacks. A lumbar puncture during a headache revealed the spinal fluid under normal pressure and negative on laboratory tests. X-ray films of the skull were negative. Electroencephalograms will be described in a succeeding article.¹

Provocative doses of 0.1 cc. of 1:10,000 and 0.05 cc. of 1:100,000 dilutions of histamine diphosphate produced violent headaches. A course of histamine "desensitization" beginning with 0.025 cc. of 1:1,000,000 dilution of histamine diphosphate, gradually increasing the dose twice daily, failed to alter the course of symptoms. Histamine administered by iontophoresis was also without effect. Doses of 0.3 and 0.1 cc. of a 1:100 dilution of histamine-azo-protein ("Hapamine") produced severe headaches within an hour after subcutaneous injections.

Various drugs were ineffective in affording symptomatic relief; these included acetylsalicylic acid, phenobarbital, pentobarbital, phenytoin sodium, ergotamine tartrate and various opiates.

Surgical section of the right middle meningeal artery was performed during an attack April 3, 1942. The previous headache had subsided by the time consciousness was regained from the intravenous pentothal sodium anesthesia. There were no abnormalities in the caliber of the middle meningeal artery or the appearance of the dura. Following this she remained symptom free for a period of three weeks but then developed frequent attacks of "tic-like" pain in the region of the right ear. On May 22, 1942 a suboccipital craniectomy with section of the right ninth nerve was performed for relief of the severe, lancinating ear pain. This operation was followed by Bell's palsy of three weeks' duration and complete relief of all head pain for five weeks. The sick headaches then returned in their former severity and frequency.

In the presence of long standing, unexplained symptoms, psychogenic factors were considered of increasing etiologic importance. A diagnosis of anxiety hysteria was made. Attempts to explain her symptoms from this point of view shamed and antagonized the patient, following which she tried, unsuccessfully, to conceal her attacks.

Because of her persistent symptoms she was finally dismissed from Nursing School in October 1942.

In mid-November 1942 she was restudied from the standpoint of allergic disease. Although foods were not suspected in relation to her attacks, she had been in the habit of drinking a quart of milk daily for many years, and beef had been her principal meat. It is of interest that during several of her more prolonged attacks she refused all food except ice cream.

Cutaneous and intracutaneous tests were negative.

She was started on a series of elimination diets at a time when the fatigue was pronounced and headaches were present every five to seven days. The initial diet eliminated milk except for that in butter, cheese and small amounts in baked goods, all cereals except rice, all meats except lamb and, in addition, eggs, legumes, citrus fruit, chocolate, nuts and condiments. On the fourth day of this diet she reported a decided general improvement, with striking relief of her dragging fatigue. She had no headaches for a period of two weeks except after one meal in which she failed to follow the diet. This contained milk in mashed potatoes and a large serving of beef.

When milk was returned to the diet after two weeks of avoidance, the first glass for breakfast was tolerated; the second glass at noon was followed in forty minutes by a violent headache during which she became semiconscious for a period of thirty minutes, the headache persisting for forty-eight hours. Returning beef to the diet in repetitive doses also produced headaches. Similar but more mild reactions followed attempts to replace chocolate, tomato and grape juice. All other foods have been taken without trouble. With the complete avoidance of listed foods she has had no unexplained headaches for the past twenty months. She was readmitted to Nursing School,

From the Allergy Clinic, Department of Internal Medicine, University of Michigan Medical School. Financed in part by Parke, Davis & Company.

1. Bagchi, B. K.: Migraine and the Electroencephalogram, to be published.

graduated, and is now regularly employed on the graduate staff. Her previous fatigue has been entirely relieved and she feels rested after the usual amount of sleep. The control of her allergic symptoms has resulted in a decided change in her personality.

The milk sensitivity in this case appeared to be one of severe and increasing degree. Although butter and cheese were originally tolerated, she began to notice headaches in January after butter and in March 1943 after cheese. A later attempt was made to include a small amount of butter in her diet. Within a few days her former fatigue returned, followed on the eighth day by a severe headache which persisted for three days. All milk products have been rigidly avoided since. Of two recent severe headaches, each beginning thirty minutes after a meal, one was traced to the ingestion of buttered vegetables and the other to the use of the small amount of milk solids contained in a teaspoon of commercial salad dressing. These were both errors made in the preparation of her special tray and were traced in retrospect after the onset of symptoms.

In November 1943 she started to work in the infants' ward. In preparing the evaporated milk formula for the day she suddenly became dizzy, developed severe pain over the right eye and in attempting to leave the room fell to the floor stuporous. Head pain and vomiting persisted for three days. She returned to the formula room on the second day, but her headache became much worse and she reported off duty. She came back on the third day and after being in the formula room forty-five minutes developed erythema, pruritus and urticaria of the exposed parts of the body.

She was unable to work with infants who were being fed evaporated milk. On three different occasions babies regurgitated on her skin; although she washed the milk off immediately, erythema developed at the sites within twenty minutes. Because of the persistent fatigue, generalized pruritus and recurrent headaches associated with work in the nursery, she was excused from these duties.

On April 22, 1944 an electroencephalogram was obtained prior to and following the ingestion of a small dose of milk taken fasting (1 cc. diluted to 100 cc. with water). To control the psychogenic factor, dilute amphetol having an identical taste and appearance (when the two samples were tested by samplers the milk was not identified) was given first, the patient understanding that she was receiving milk. Forty-five minutes later she developed mild twitching of the right upper lid and nausea which lasted twenty minutes. No other symptoms occurred during a period of ninety minutes.

She was then given 1 cc. of milk in water, understanding that she was receiving a second dilute dose. Ten minutes later she developed throbbing right temporal pain which became progressively more severe. On two occasions in the following five hours at the height of her agonizing pain she lapsed into semiconsciousness for several minutes. The headache syndrome persisted two days, the residual fatigue for an additional day.

Cutaneous tests with raw milk and the standard milk extract were again performed July 20, 1944 and found negative. One-half hour later 0.02 cc. of a 1:10 dilution of the scratch test material (the standard intracutaneous test for milk) was injected intradermally. Ten minutes later she noted flushing and itching of the anterior part of the neck and face; this became generalized in the next five minutes. Epinephrine hydrochloride 0.5 cc. in a dilution of 1:1,000 was then administered subcutaneously, following which the erythema and pruritus gradually disappeared. Thirty minutes after the intracutaneous test she developed mild right frontal head pain, which became progressively more severe. Nevertheless she reported on duty two hours after the test, starting an operation as a surgical nurse. During the operation the pain became extreme and was associated with severe dizziness. Without warning, except for a transient sensation of faintness, she fell to the floor two hours and thirty minutes after the skin test. Although altered consciousness persisted for only two or three minutes, headache, dizziness, nausea and weakness continued, making it necessary to report off duty. With rest, all symptoms except for residual fatigue subsided after a duration of three and one-half hours.

The intracutaneous test site was negative when read at twenty minutes and remained so throughout the headache. After the head pain had subsided she noticed mild pruritus at this area, followed by erythema 2 cc. in diameter, which reached a maximum between six and seven hours after the injection. A wheal was not observed at any time and there was very little edema as judged by the insignificant degree of elevation. The site was negative the following morning and remained so thereafter. There were no delayed reactions at the scratch test sites.

COMMENT

This case illustrates how the diagnosis of allergic headaches may be missed by the routine allergic investigation including history, skin tests and the trial of elimination diets for short periods when the incidence of the attacks is greater than once in two weeks. No clues were obtained from the past and family history, as they were both negative for other allergic manifestations. This, however, is not an uncommon finding, and one must always be alert to the possibility of the initial allergic expression.

It is of interest that milk, the major offending food, had been received in large amounts daily for many years and that beef had been the principal meat of the diet. This is such a common observation, notwithstanding the fact that acute episodes may occur only occasionally, that the elimination of those foods eaten most frequently and in greatest abundance sometimes results in improvement, giving clues to the major offenders.

Cutaneous tests to the common allergens were negative in 1939, cutaneous and intracutaneous tests were again negative in 1942, and both cutaneous and intracutaneous tests with milk were negative in 1944 as these reactions are customarily read. The last intracutaneous injection of milk was followed by a constitutional reaction and headache, following which there was a moderate delayed reaction at the test site. The absence of skin tests with milk, as performed and read by standard technic, is in striking contrast to the extreme and increasing degree of milk sensitivity. This case affords additional evidence of the general unreliability of the skin test as a diagnostic method in food allergy.

The production of severe symptoms by the subcutaneous injection of 0.1 cc. of a 1:10,000 dilution of histamine diphosphate is suggestive of "histaminic cephalgia" as described by Horton.² In fact, this is the minimal provocative dose recommended by him as a diagnostic measure. It is of interest that a twenty-fold diminution in dosage (0.05 cc. of a 1:100,000 dilution) also produced an abrupt and violent attack, identical as far as could be determined with the attacks occurring after the ingestion of milk. Repeated efforts to "desensitize" with histamine by daily and twice daily injections failed to alter the general course of the headaches.

The fact that the patient was temporarily improved after extensive surgical procedures is not an uncommon finding. Relief of symptoms from four to six weeks after surgery of various types is not an infrequent experience in dealing with allergic manifestations.

The severity of the cephalgia and the close relationship of the violent pain with periods of altered consciousness or stupor are unusual features of this case. It is of interest that the patient never had an attack of altered consciousness which was not associated with severe headache. From the clinical standpoint it appeared that she lapsed into a state of altered consciousness as a result of the severity of the pain. Although slightly suggestive from the standpoint of the mode of onset, the features of these bouts of semiconsciousness were not typical of a convulsive disorder such as epilepsy. The interpretation of the electroencephalograms is of interest in this respect.³

The "fatigue unrelieved by rest" occurring in this case both during and between attacks of headaches deserves emphasis, as it must be considered an expression of the uncontrolled allergic reaction. This symptom was first described by Rowe⁴ in 1930 and called allergic toxemia. He⁴ has observed that it

3. Rowe, A. H.: Gastrointestinal Food Allergy: A Study Based on 100 Cases, *J. Allergy* 1: 172, 1930.

4. Rowe, A. H.: Allergic Toxemia and Migraine Due to Food Allergy, *California & West. Med.* 33: 785, 1930.

is frequently associated with head pain of allergic origin. It is a common symptom resulting from intolerance to foods and may be associated with any of the clinical manifestations of allergy.⁵ In an occasional case it may be the only evidence of allergic imbalance at the time the patient is seen. In a recent survey⁶ periods of this type of fatigue were found to occur more commonly in persons with a positive past history of allergy than in a control group with negative histories of allergic disease. "Fatigue unrelieved by rest" is so frequently associated with the allergic headache that relief of the former as the result of an elimination diet is often the first evidence of an allergic causation of the latter.

The common features of the fatigue and weakness of the uncontrolled allergic reaction, as illustrated in this case, and the debility of the patient with neurasthenia must be carefully differentiated. This is obviously difficult to do and in some cases, particularly if the allergic reaction is of long standing, both factors may be present. The fact remains, however, that fatigue as a symptom of the allergic reaction has received little emphasis and is not generally appreciated in contrast to the more widely known relationship of fatigue as a manifestation of a psychogenic disturbance.

This case is a good example of long standing incapacitating headaches in which the absence of apparent organic cause led to the assumption that the headaches were of psychogenic origin. It should be recalled that there are no measurable residual structural effects as a result of multiple attacks of allergic head pain. The possibility that headaches may be of allergic origin should be considered prior to establishing the diagnosis of psychogenic headaches.

SUMMARY

A case of allergic headache of unusual severity associated with fatigue and a state of altered consciousness resulting from sensitization to milk illustrates many of the pitfalls in the recognition and specific diagnosis of allergic head pain.

700 North Michigan Avenue.

Council on Foods and Nutrition

With the increasing emphasis being placed on vitamins in nutrition the practice of adding these substances to many foods has become widespread. Fresh milk has been one of the foods to which the addition of several vitamins as well as minerals has been advocated. Several products of this type are now on the market. The Council has authorized for publication the following report discussing this principle of milk fortification.

GEORGE K. ANDERSON, M.D., Secretary.

FORTIFICATION OF MILK WITH VITAMINS AND MINERALS

For several years the practice of fortification of milk with vitamins and minerals has been increasing. The tendency exists to have a retail unit of milk contain the full daily requirement of most of the vitamins and minerals for which requirements have been stated by the Food and Drug Administration. On several occasions the Council on Foods and Nutrition has been requested to express an opinion concerning these fortifications.

Several years ago the Council stated a policy of encouraging restorative additions of dietary essentials to foods to recognized high natural levels, provided the additions are limited to essentials for which a wider distribution is considered to be in the interest of public health. On several occasions the Council has reaffirmed this policy. The Council has accepted and encouraged the fortification of milk with vitamin D well beyond any natural level because of the belief that such fortification is in the interest of public health. Vitamin D is not present in important amounts in a customary diet unless fish oils are

included. Milk is an ideal carrier of vitamin D because of its content of calcium and phosphorus, with the utilization of which vitamin D is directly concerned. The Council has not approved any other addition to milk.

A fortified milk has been submitted to the Council for acceptance. With the exception of ascorbic acid, each quart of this product contains the minimum daily adult requirement of those vitamins and minerals for which the Food and Drug Administration has established requirements, and in addition it contains 10 mg. of niacin. The label (bottle cap) statement of content is as follows: vitamin A, 4,000 units; thiamine, 1 mg.; riboflavin, 2 mg.; vitamin D, 400 units; niacin, 10 mg.; calcium, 1 Gm.; phosphorus, 0.8 Gm.; iron, 10 mg.; iodine, 0.1 mg. Of these components the entire amounts of calcium and phosphorus are natural to the milk and do not represent additions. All other materials are added in whole or in part.

The question arises as to whether it is in the interest of public health to fortify milk with vitamin A, thiamine, riboflavin, niacin, iron and iodine or any one of these materials.

The vitamin A content of milk varies with the feed of the cow. Winter milk of barn fed cows contains approximately half as much vitamin A as does the milk of cows on good pasture. With this wide range of content, fortification such as would insure a minimum content of 4,000 units to the quart must be with an amount which would be certain to raise to this level those milks with the lowest values. In a considerable proportion of instances the addition would be in excess of the need, particularly in the summer when the natural content of milk is at its maximum. In at least a commercial sense this excess would be wasted.

Some vitamin A deficiency has been shown to exist in this country. Such deficiency as exists is to be found chiefly at the lowest economic levels. In the surveys reported by the U. S. Department of Agriculture (Miscellaneous Publication Number 452, 1941) among nonrelief families in all sections of the country, intakes of vitamin A less than 5,000 units daily are recorded for only two of thirty-seven groups. In both instances the weekly expenditure for food was less than \$2.08 for each person. Such persons are not likely to buy milk sold at a premium. Those who consistently use milk are likely to be ingesting diets of good quality and therefore of good vitamin A content. It appears that little public health need exists for fortification of milk with vitamin A. Such need as may exist is insufficient to warrant Council acceptance of milk so fortified.

The thiamine content of milk varies, but 0.38 mg. to the quart may be considered as an approximate average, with about 10 per cent loss with pasteurization. This amount is more than that required for the metabolism of milk. Milk more than carries its own load as regards thiamine. Any fortification would be for the purpose of covering the deficits of other foods. Such deficits as may occur are chiefly those associated with the refinement of foods, especially cereal foods. Much effort is being expended on a national scale to restore to cereal foods those nutritional essentials which have been lost in the processing. This is a laudable effort which deserves every encouragement. Cereals are much more important as a vehicle for added thiamine than is milk. Almost every one eats cereal in some form, whereas unfortunately milk does not yet have universal use. Those in the lower economic levels are the ones who subsist importantly on cereal foods and are the ones who are less likely to use milk. The greater the addition to the cost of milk because of fortification, the less likely are those who need it most to get it. It is concluded that public health need is not particularly well served by the fortification of milk with thiamine and that such need as may exist is not sufficient to warrant Council acceptance of thiamine fortified milk.

An average content of riboflavin in milk is approximately 1.8 mg. to the quart, an amount which is four to six times that required for metabolism of the milk. While liver and yeast are excellent sources of riboflavin, milk is the only common food likely to be ingested daily which supplies a high proportion of the requirement for this material. The same type of discussion as given for thiamine fortification of milk applies also to fortification with riboflavin. The fortification of processed cereal foods with riboflavin is considered to be more useful and more effective in supplying the riboflavin needs of the popu-

lation than is the fortification of milk. It is concluded that such need as may exist for the fortification of milk with riboflavin is not sufficient to warrant Council acceptance of riboflavin fortified milk.

Despite its low niacin content, milk has long been known as a food useful in a pellagra preventive diet. Pellagrins are not milk drinkers. Niacin deficiency has not been recognized in those who ingest diets which are average for the country as a whole. Niacin is sufficiently plentiful in meat and fish and in potatoes, tomatoes, peas and other vegetables to insure against deficiency. The foods mentioned are commonly eaten, some of them daily. The enrichment of family flour and baker's bread with niacin is now common practice. The addition of niacin to milk does not seem to be the answer to the problem of correcting such niacin deficiency as exists. The public health need for addition of niacin to milk is not such as to warrant Council acceptance of milk so fortified.

A diet containing meat, eggs, green vegetables and whole grain or enriched flour and bread amply supplies the iron requirement. Despite the fact that milk is a poor source of iron, no indication is evident that the fortification of milk with iron serves a useful purpose. The restoration of iron in processed cereal foods is more definitely indicated. Those who eat the largest quantity of cereal foods are, in general, the ones who ingest the least milk. Those who include milk in their diets are usually of an economic and social status in which people generally include iron-containing foods. The public health need for fortification of milk with iron is not sufficient to justify Council acceptance of milk so fortified.

The iodine content of milk varies from a negligible amount to 2 mg. or more to the quart, depending on the iodine content of the food of the cow. Except in regions where goiter is prevalent, milk usually may be depended on to contain in each quart at least 0.1 mg., the amount stated by the Food and Drug Administration as the minimum daily requirement and also the amount which is added to the fortified milk under discussion. In regions where iodine is deficient, the addition of iodine to the diet by some means is highly desirable. It has now become a generally accepted concept that the most effective method of insuring an adequate iodine intake in regions where this element is deficient is to add iodine to some food which is eaten daily by every one. Table salt has been selected as the appropriate food. It seems unwise to sanction the addition of iodine to more than one food. Some years ago the Council published its decision that foods other than table salt fortified with iodine are not eligible for acceptance. No reason for altering this decision has developed.

Multivitamin preparations have come into general use and are now included in the U. S. Pharmacopeia. The use of milk as a vehicle for these same vitamins may seem reasonable at first thought. However, it is appropriate to consider that the use of multivitamin preparations is a therapeutic measure and is to be sanctioned only under special circumstances. The special situations which have been listed by two of the Councils of the American Medical Association (The Proper Use of Vitamins in Mixtures, THE JOURNAL, July 18, 1942, p. 948) are essentially the treatment of deficiency states, supplementation of reducing diets for obesity, supplementation of restricted diets used for the treatment of allergy, supplementation of restricted diets during convalescence from severe infections, supplementation of special diets for peptic ulcer, and infant feeding. The use of special multivitamin preparations in normal infant feeding is unnecessary. Except for infant feeding, all the situations mentioned are in the treatment of abnormal conditions. The use of multivitamin preparations in normal nutrition is not only unnecessary but conflicts with the teaching of good nutritional practice. The same logic applies to the addition of minerals to the diet. It is to be assumed that the fortified milk under consideration is intended chiefly for use in the normal diet and not primarily for treatment of abnormal states. Such use does not conform to general principles acceptable to the Council.

From the preceding discussion it is concluded that the fortification of milk with vitamin A, thiamine, riboflavin, niacin,

iron and iodine or any one of these materials does not serve a public health need sufficiently to warrant Council acceptance of the fortified product.

D-Q (DAILY QUOTA) MILK OF THE BORDEN COMPANY NOT ACCEPTABLE TO THE COUNCIL

This milk product, which is being marketed in several areas in the East, has been fortified by the addition of vitamins and minerals to contain the following amounts of these nutritional elements per quart:

Vitamin A	4,000 U. S. P. units
Vitamin D	400 U. S. P. units
Thiamine	1.0 mg.
Riboflavin	2.0 mg.
Niacin	10.0 mg.
Iron	10.0 mg.
Iodine	0.1 mg.

As shown in the foregoing report, the addition of these nutrients to milk with the exception of vitamin D is not considered to be necessary in the interest of the public health or to conform with the general principles of nutrition advocated by the Council. Therefore D-Q milk is declared not acceptable.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN E. SMITH, M.D., Secretary.

MERBROMIN (See New and Nonofficial Remedies, 1944, p. 139).

The following dosage forms have been accepted:

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK
Merbromin Crystals: 10 Gm., 100 Gm., 500 Gm. and 1,000 Gm. bottles.

Solution of Merbromin—N. F.: 7.5 cc., 15 cc., 30 cc., 473 cc. and 3,785 cc. bottles.

Surgical Solution of Merbromin—N. F.: 473 cc. and 3,785 cc. bottles.

VITAMIN D (See New and Nonofficial Remedies, 1944, p. 624).

The following additional dosage form has been accepted:

WINTHROP CHEMICAL CO., INC., NEW YORK

Capsules Drisdol Concentrated Solution in Oil: 5 minims. Each capsule contains 1.25 mg. of Drisdol and has a potency of 50,000 units of vitamin D (U. S. P.).

TETRACAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 88).

The following additional dosage form has been accepted:

WINTHROP CHEMICAL CO., INC., NEW YORK

Ampuls Pontocaine Hydrochloride "Niphanoid" for Spinal Anesthesia: 250 mg. Ampuls containing tetracaine hydrochloride in finely divided and instantly soluble form.

ESTROGENIC SUBSTANCES (See New and Nonofficial Remedies, 1944, p. 414).

The following additional dosage form has been accepted:

GEORGE A. BREON & CO., KANSAS CITY, MO.

Solution of Estrogenic Substance (in oil) with Chlorobutanol 3%: 10 cc. vial. Each cubic centimeter contains 20,000 international units of estrogenic substance and chlorobutanol 3 per cent.

SATURDAY, OCTOBER 14, 1944

AMERICAN PUBLIC HEALTH ASSOCIATION HEALTH INSURANCE DECLARATION

At its annual meeting in New York, October 4, the Governing Council of the American Public Health Association adopted a report favoring in effect a federal plan of compulsory health insurance. The text of the adopted report appears elsewhere in this issue (page 441). This report, first prepared by a subcommittee,¹ was approved after several amendments by the association's Committee on Administrative Practice.² The proposed medical service would be supported by social insurance, supplemented by general taxation, or by general taxation alone.

The ratification of the report as amended came after extended debate in which there was opposition to the adoption and publication of the report as a stated policy of the association. Those who opposed pointed out (a) that the administration of public health in the United States was by no means so universal or so generally adequate that public health departments in general were ready for this step, (b) that before the association placed itself publicly on record in the terms of this report there should be consultation with the most interested professional groups, particularly the American Medical Association and the American Dental Association, and (c) that the publication of the subcommittee report, its approval by the Committee on Administrative Practice and the call for adoption in the Governing Council occurred within less than thirty days elapsed time, although the subcommittee had been working on the report for a year.

1. Joseph W. Mountin, M.D., chairman, Earle G. Brown, M.D., David D. Carr, M.D., Edwin F. Daily, M.D., Graham Davis, I. S. Falk, Ph.D., J. Roy Hege, M.D., Hugh R. Leavell, M.D., Emory Morris, D.D.S., George St. J. Perrott, Marion G. Randall, R.N., Edward S. Rogers, M.D., and Nathan Sinai, D.P.H.

2. Wilton L. Halverson, M.D., chairman, Haven Emerson, M.D., vice chairman, Reginald M. Atwater, M.D., secretary, Gregoire F. Amyot, M.D., Dwight M. Bissell, M.D., George B. Darling, D.P.H., Lloyd M.D., Millard C. Hanson, M.D., Ira V. Hyscock, Sc.D., J. Graves, M.D., Joseph W. Mountin, M.D., John T. Pharr, Kenneth F. Maxey, M.D., W. S. Rankin, M.D., Clarence M.B., D.P.H., George H. Ramsey, M.D., and H. A. Whittaker L. Scamman, M.D., Marion W. Sherman, R.N., and H. A. Whittaker

The motion to adopt the report was made at the October 2 meeting of the Governing Council and was extensively debated at that time. Action was postponed until the October 4 meeting. At that time an amendment was offered to the motion to adopt. This amendment called for the Governing Council to receive this portion of the report of the Committee on Administrative Practice and to refer it to the Executive Board of the American Public Health Association with instructions to confer with the Board of Trustees of the American Medical Association and with the American Dental Association in an attempt to arrive at a statement which these three great professional groups could support. The amendment was lost by a standing vote approximately three to one after a voice vote had left the chair in doubt. The Governing Council then proceeded to vote on a motion to adopt the report; this vote was 49 Aye and 14 No. The opposition to the adoption of the report was led by Drs. Walter A. Biering, Past President of the American Medical Association, Haven Emerson and W. W. Bauer.

Now what is the group that adopted this report? Of the 7,493 members of the American Public Health Association 1,571 are Fellows. Only Fellows have a right to vote for governing councilors; the vote is conducted by ballot given to each Fellow when he registers at the meeting; Fellows not in attendance do not have a vote. The Governing Council consists of approximately 100 members, of whom 30 are elected by vote of the Fellows, 10 each year for three year terms, the rest of the members of the Governing Council hold membership by virtue of being section officers or representatives of affiliated (mostly state) public health associations. Members of the association other than Fellows can vote only on section affairs. The report on compulsory health insurance represents, therefore, the action of the subcommittee which prepared it, the Committee on Administrative Practice which approved it and the 49 members of the Governing Council who voted in its favor. Here is not a democratic practice in action; here is a shrewdly manipulated performance by full time public officials, economists, bureaucrats. Most of the names of those on the subcommittee are those of men long committed to federal compulsory sickness insurance and to federal control of all matters in the health field.

The American Public Health Association has an obvious right to express itself on any subject related to the public health. The rejection by the majority group of the proposal for consultation with medical and dental leaders indicates the attitude that may be expected of them if they should have control of the Washington bureaucracy that would dominate American medicine should their ideas become effective. Perhaps this step in which these men had leadership will be useful in

serving notice once more on the medical, dental, nursing, pharmaceutical and other professional groups as to the nature of the political manipulators in the fields of social security and public health whom the medical professions will be forced to combat.

PROLONGING THE ACTION OF PENICILLIN

Penicillin injected intramuscularly is rapidly absorbed by the local capillaries, the penicillin titer of the blood stream usually reaching its maximum within fifteen minutes. Half of the absorbed penicillin is excreted by the kidneys or otherwise removed from the circulation within the next fifteen minutes. The penicillin titer falls to one fourth of the maximum by the end of one hour and to zero by the end of two hours. To prolong the therapeutic period, repeated intramuscular injections or continuous intravenous instillations of penicillin have been tried.

Renal excretory blockade by the simultaneous injection of penicillin and diodrast or penicillin and p-aminohippuric acid have been suggested to accomplish the same purpose.¹ More recently a slowing and prolongation of penicillin absorption from the injected muscle by suspending penicillin in inert protamine, oil or wax has been tried by Romansky and his associates² of the Walter Reed General Hospital. In their initial experiments penicillin was suspended in peanut oil, sesame oil, cottonseed oil, castor oil or protamine zinc and the suspension injected intramuscularly into rabbits. A distinct prolongation of therapeutic blood titer resulted from this technic, with a parallel prolongation of penicillin excretion in the urine.

Following reported prolongation of the action of desoxycorticosterone acetate,³ histamine⁴ and heparin⁵ by the use of beeswax, Romansky suspended penicillin in a mixture of from 0.75 to 6 per cent beeswax in peanut oil. Several rabbits were injected intramuscularly with 5,000 to 10,000 Oxford units of penicillin in 1 cc. of this mixture, and an equal number of control rabbits were injected with the same number of units in saline solution. In none of the control animals was a therapeutic level of penicillin maintained in the blood for as long as two hours. In rabbits injected with the penicillin-beeswax-peanut oil mixture an adequate therapeutic level was maintained for from six to twelve hours. This is a greater prolongation of penicillin action than previously obtained with unmixed oils.

Patients were then given intramuscular injections of about 50,000 Oxford units of penicillin in 2 to 2.5 cc. of beeswax-peanut oil. In these patients an effective therapeutic blood titer was maintained for six to seven hours while penicillin excretion in the urine continued for twenty to thirty-two hours. The therapeutic efficiency of this technic was then tested on 12 patients with gonococcic urethritis, 11 of whom were cured by a single intramuscular injection with the penicillin-beeswax-peanut oil mixture. Fifty-three additional patients with gonorrhea were similarly cured by a single intramuscular injection by other members of the staff of Walter Reed General Hospital. Detailed reports are promised for the near future.⁶

PULMONARY TUBERCULOSIS OF BOVINE ORIGIN

At the London Congress on Tuberculosis in 1901 Koch asserted that bovine tubercle bacilli are virtually nonpathogenic for man and that measures to protect human populations against tuberculosis of bovine origin are unnecessary. Following repeated demonstrations by other investigators of bovine tubercle bacilli in glandular tuberculosis in children, Koch modified this view. At the Washington congress in 1908 he admitted that bovine tubercle bacilli might have sufficient virulence to cause local glandular lesions in man but still asserted that they are never sufficiently virulent to cause human pulmonary tuberculosis. By that time only 2 possible cases of human pulmonary tuberculosis of bovine origin had been reported in the literature, 1 of which was doubtful.

During the next fifteen years work by the scientific staff of the Royal Commission on Tuberculosis of Great Britain under the leadership of the late A. Stanley Griffith seemed to confirm Koch's view. Bovine tubercle bacilli were demonstrated in the sputum of only 4 of the 266 cases of human pulmonary tuberculosis examined by the British clinicians. Since then, however, the accumulated evidence has pointed to a quite different conclusion. From the sputums of 6,963 cases of human pulmonary tuberculosis in Great Britain, Griffith and his associates¹ have cultivated and identified bovine tubercle bacilli in 241 cases, or 3.4 per cent of all cases examined.

The relative frequency of bovine infections was highest in Scotland, reaching 25.8 per cent in the Orkney Islands and falling to 9.1 per cent in adjacent districts of the mainland. The average for all of Scotland was 5.2 per cent, falling to 4.4 per cent in the city of Aberdeen. In England the highest frequency (2 per

cent) was recorded in the north and middle counties, southern England yielding only 0.6 per cent.

Five of the 266 cases were double infections, the bovine bacilli being associated with tubercle bacilli of human type. Clinical and anatomic evidence, such as previous cervical or mesenteric glandular tuberculosis or bone and joint tuberculosis, was strongly in favor of the digestive tract as the usual channel of entry of the bovine bacilli. Personal histories left little doubt that raw cow's milk was the main source of infection in the majority of cases. The probability of human to human infection with the bovine bacillus was ruled out in all but 4 cases. One probable instance of infection with bovine bacilli spreading from man to cattle was recorded.

The British survey led to the conclusion that cases of tuberculosis of the lungs due to bovine tubercle bacilli are indistinguishable clinically, radiologically or by postmortem examination from cases due to the human tubercle bacilli. From this Griffith concludes that human and bovine tubercle bacilli are equally pathogenic for man. This is but a belated endorsement of the opinion long held by American pathologists, many of whom² believe that the bovine bacillus is often more highly virulent for man than the average human strain.

Griffith closes his posthumous report with a plea for avoidance of the consumption of raw milk in Great Britain, which is currently causing an estimated annual loss of 2,000 human lives in Scotland and England, two thirds of them of children under 15 years of age.³

THE REVERSIBILITY OF HEART DISEASE

Recently Dr. Paul Dudley White¹ called attention to the extent of the reversibility of heart disease in the annual oration in medicine before the Illinois State Medical Society. Twenty years ago Hamilton and Lahey² proved that serious thyrocardiac disease, now almost unknown, could be dispelled by subtotal thyroidectomy; the cardiac enlargement and failure in such cases had previously been considered risks too hazardous for surgery. Since that time every kind of heart disease has been shown to be reversible, in at least a small proportion of cases, either spontaneously or by surgical or medical treatment. This is a different situation from that recalled by White, who states that some thirty years ago when he was medical student, intern and hospital resident "it was still being taught and believed that heart disease was final and fatal, that the coronary arteries were forever 'end arteries'".

and that at best we could simply delay a little the day of dissolution and make a bit more comfortable the remaining hours of the victims."

Following the demonstration of the reversibility of thyrotoxic heart disease and of the cardiac enlargement of myxedema, the reversibility of various other conditions has been proved. In 1928 the first case in this country of cure of chronic constrictive pericarditis by pericardial resection was carried out by Churchill; since that time relief has been given in many other cases. Some ten years ago it was realized that cardiac dilatation due to acute rheumatic myocarditis could entirely subside with the disappearance of mitral diastolic as well as of mitral systolic murmurs. Aneurysms, sacular and arteriovenous, have been attacked successfully by wiring or excision. Coronary heart disease, one of the most important of all types, has been shown to be reversible also, primarily through the spontaneous development of an adequate collateral circulation. Thus myocardial infarction and indeed also angina pectoris in many cases may exist merely as acute or subacute illnesses and not necessarily as chronic disabilities. The acute cor pulmonale consisting of dilatation of the right heart chambers may quickly subside on recovery from the immediate effects of massive pulmonary embolism. Cardiac dilatation and even failure found in acute hemorrhagic nephritis, avitaminosis of the B₁ type and severe anemia may also subside, with recovery from these underlying diseases.

Six years ago congenital heart disease joined the ranks of the types of reversible heart disease, when Gross³ of Boston successfully ligated the patent ductus arteriosus; since then, in a good many cases, cardiac strain and dilatation have been relieved by this procedure. Subacute bacterial endocarditis has been yielding slowly but definitely to chemotherapy, first in slight degree to the sulfonamides and now apparently more successfully to massive doses of penicillin. Finally, the last of the types which was thought not long ago to be particularly irreversible, namely hypertensive heart disease, is now being relieved on occasion by the more extensive splanchnic resection carried out by Smithwick.⁴

Dr. White concludes: "Where does this all lead us? In two directions: first and most obviously, along our continued optimistic search for still further chances and methods of reversing the evidences of heart disease, and second and still more importantly, in our attacks on the causes of heart disease, such as hypertension, before the heart itself is affected. That is our ultimate goal in cardiology, as in all fields of medicine, prevention rather than cure!"

Current Comment

SHOCK THERAPY FOR DEMENTIA PRECOX

Patients with dementia precox treated by insulin shock at the Brooklyn State Hospital, New York, did substantially better in all respects than comparable patients who did not receive any form of shock therapy. This fact, based on a study of 1,128 patients with dementia precox treated with insulin shock therapy and 876 not treated with shock therapy was embodied in a report recently submitted by the Temporary Commission on State Hospital Problems in New York State.¹ Among the benefits of insulin shock treatment was the consistently higher proportion of insulin treated patients who were returned to gainful employment. A much larger proportion of the treated patients were able to leave the hospital; the hospitalization period prior to release was 3.8 months shorter per patient among the insulin treated group than among the nontreated. The report pointed out that insulin treatment thus effected a saving of 286,695 days of hospital care. The recommendation of the commission was that insulin shock therapy should be made available to all patients with dementia precox in state hospitals in New York.

ASCORBIC ACID FOR BLEEDING GUMS

A number of reports have indicated that ascorbic acid is valuable for various forms of gingivitis and bleeding gums. Consequently vitamin C frequently has been administered for that purpose. The Royal Air Force, for example, has used large quantities for the treatment of all forms of bleeding gums. Now a report has appeared based on an investigation carried out between October 1941 and May 1942 to discover the incidence of bleeding gums in the Royal Air Force and to evaluate the use of ascorbic acid in the treatment of this condition. The total number of personnel under investigation was 2,962 at four stations. Of these, 588 had some degree of bleeding of the gums, or a percentage of 19.8. The gums of the lower jaw were examined for bleeding after digital massage. Bleeding was recorded as of three degrees: (a) bleeding just perceptible at one or two points after firm massage, (b) bleeding more easily produced or bleeding from several points and (c) bleeding apparent on inspection or at the slightest touch. An average amount of ascorbic acid present in the food served to the airmen at three of the stations was 25.8 mg. per man daily during October and November 1941 and 16.8 mg. during March 1942. Alternate members of the group with bleeding gums were given ascorbic acid tablets and dummy tablets. The dose was 200 mg. of ascorbic acid daily for seven days followed by 100 mg. daily for fourteen days. Of one group of men with bleeding gums, 250 completed the test, 119 receiving ascorbic acid and 131 receiving dummy tablets. There was no greater improvement in the gum conditions observed in those treated with

ascorbic acid than in those who received the control tablets. In one of the stations, observations were carried out on 600 men over a six weeks period. There was a large normal variation in the degree of bleeding of the gums, irrespective of treatment. Those having "sponginess" as well as bleeding of the gums did not show any greater improvement with ascorbic acid treatment than with dummy tablets. The personal opinions of patients with regard to the degree of bleeding from the gums and effectiveness of treatment did not bear any relation to the objective signs. Stamm and his colleagues¹ concluded that greater improvement in the gum condition was not obtained by treatment with ascorbic acid than with dummy control tablets. In view of the shortages in vitamin C supplies, it seems advisable to use ascorbic acid in the future with more discrimination. Large supplementary doses may be limited to those conditions for which scientifically acceptable evidence establishes the value of vitamin C.

TRANSLATION OF MEDICAL BOOKS FOR LATIN AMERICAN USE

Important books of this country, particularly in the fields of science, medicine and technology, will be made more readily available in Spanish and Portuguese translations for peoples of the other American republics as the result of a project to be conducted by Science Service, the nonprofit scientific institution, as a part of the Department of State's broad program for intellectual cooperation in the Western Hemisphere. Spanish and Portuguese translations of American books, issued by publishers in the other American republics as well as by United States publishers, will receive financial aid under this project. Books originally published in Spanish and Portuguese will be made available in English in the United States under provisions for similar aid to United States publishers. A grant-in-aid by the Department of State provides Science Service with funds to help defray the costs of translations, to obtain and distribute copies of the translated books to libraries, institutions and other organizations and to cooperate otherwise in making the literature of any one American republic available to other peoples on the two continents. The purpose of this two way translation program is "to overcome the barriers raised by difference of language by making available to the peoples of the other American republics the writings which represent the thought and the cultural and intellectual life of the United States, and making available to the people of the United States the writings which represent the thought and cultural and intellectual life of the peoples of the other American republics." Suggestions as to translations needed are being received from officials, scientists, educators, publishers and others in this country and the other American republics. This program should contribute materially to the increasing interdependence and good will of physicians and scientists in our own country and in our sister republics.

MEDICINE AND THE WAR

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

POLICY STATEMENT

Paul V. McNutt, chairman of the War Manpower Commission, issued the following statement on the policy adopted by the directing board of the Procurement and Assignment Service of the War Manpower Commission at a meeting on September 23:

"The war is not yet over and we must continue our efforts to keep the armed services supplied with a sufficient number of doctors, dentists and nurses to meet the critical needs of this period of the war and also fulfil our obligation to the home front.

"In common with the other divisions of the War Manpower Commission, however, the Procurement and Assignment Service is cooperating with those charged with the responsibility for developing demobilization plans. In view of the information collected incident to the mobilization of our medical resources for war, this office can perform many useful services in connection with these demobilization plans in the interest of the members of the professions now in service. The War Manpower Commission wishes to be of whatever service possible but, in common with all war agencies, has no interest in perpetuating its controls beyond the period necessary."

In order that the point of view of the directing board of the Procurement and Assignment Service may be understood by

the doctors, dentists, veterinarians, sanitary engineers and nurses, the following statement of policy was adopted at its meeting on September 23:

1. The Procurement and Assignment Service is an organization which was created at the request of these professions to meet a war problem, and in meeting its responsibilities this service has had the support of these professions.

2. As a war agency this service is discharging and will continue to discharge its obligations until the end of the war. It will cooperate with the agencies concerned with the effective utilization of the individual members of these professions who are demobilized before the end of the war.

3. In the directive under which it was created, the responsibilities of the Procurement and Assignment Service did not extend beyond the duration of the war.

4. Therefore it does not contemplate dealing with peacetime demobilization but will continue its activities, including cooperation with agencies working on demobilization plans, so long as the war continues.

The members of the directing board are Drs. Frank H. Lahey, chairman, Harvey B. Stone, vice chairman, C. Willard Camalleri Jr., Harold S. Diehl, James E. Paullin and Abel Wolman.

NAVY

NAVY RELIEF SOCIETY ASSISTANCE IN MEDICAL CARE OF NAVAL DEPENDENTS

The primary purpose of the Navy Relief Society, incorporated Jan. 23, 1904 under the Laws of the District of Columbia, is to assist, in time of emergency need, the widows, minor orphans and dependent mothers of deceased men of the Navy and Marine Corps. It is also its purpose, in cases of emergent need, to help active servicemen provide hospital, medical and surgical care for their dependents when they and their families are unable to do so with their own resources. This financial assistance takes the form of a loan, without interest, or a gratuity, or a combination of the two, depending on the man's ability to repay a loan without undue hardship.

The Navy Relief Society is not a government agency. Its funds are raised by voluntary contributions, largely from service personnel, except that the general public contributed during the year 1942.

The society deems it unwise to make loans that cannot be repaid, and its funds are not adequate to permit it to assume the obligation to advance, as a gratuity, sufficient funds to pay in full normal medical and surgical fees, but it does desire to help the serviceman to meet such emergency needs of his dependents.

It is the policy of the society to help active servicemen secure hospital (open ward rates), medical and surgical care for their dependents in cases of other than chronic illness, provided (a) the serviceman and his family do all that they can to meet their own obligations, (b) the resources of the community are utilized as far as possible, without prejudice to the status of the family prior to the man's entry into the service, and (c) the application for assistance has been approved by the Navy Relief Society before the services are rendered, except in emergency cases, when application must be made within forty-eight hours to the Navy Relief Society directly, through its auxiliaries or through the American Red Cross.

The Navy Relief Society may, after full consideration of the facts of the case, help a serviceman provide hospital, medical

and surgical care for his dependents, but it cannot (a) accept the obligation to advance as a gratuity (gift) sufficient funds to pay in full normal medical and surgical fees, (b) pay bills for operations or medical care in chronic cases or (c) pay hospital, medical or surgical bills contracted without its knowledge or approval, except under conditions stated in c in the preceding paragraph.

It is expected that physicians and surgeons will arrange with the family for the payment of their fees. When the dependent or the man concerned needs assistance, application should be made by the man or his dependent to the Navy Relief Society directly or through its auxiliaries or through the American Red Cross prior to creating the obligation.

The society will usually agree to assist, but the extent to which the society is able to assist is limited and will be based on the full consideration of all the facts in the case. As a rule the assistance will be rendered by sending to the patient, for delivery to the physician or surgeon, a check drawn in favor of the physician or surgeon.

CAPTAIN ALPHONSE McMAHON HONORED

Capt. Alphonse McMahon, St. Louis, recently returned from eighteen months' service in the South Pacific and is now on duty at the U. S. Naval Hospital at the National Naval Medical Center, Bethesda, Md. He was recently honored by the Mississippi Valley Medical Society as its distinguished service award recipient for 1944. The award, a gold medal and certificate, was presented by the society's president, Dr. C. Paul White, September 27. The citation accompanying the award read, in part, "To Captain Alphonse McMahon of St. Louis, Medical Corps, U. S. Navy, for his long service as a teacher of clinical medicine at St. Louis University Medical School; for his continuous interest in postgraduate medical education, in recognition of which he was elected Vice President of the American Medical Association and President of the St. Louis Medical Society a few years ago, and for his fine example as a citizen of the United States by leaving a lucrative private practice promptly on declaration of World War 2 and entering the

U. S. Navy although over the draft age. Here he spent eighteen months in the South Pacific in the establishment of one of the first hospitals to receive combat injured from the battles of the Coral Seas and Guadalcanal, in recognition of which he has been cited by Admiral William F. Halsey as a naval officer who has "reflected great credit on himself by his outstanding professional ability and keen judgment, particularly in the management of war wounds and in the treatment of tropical diseases. His long experience as a teacher of medicine and his effective leadership in the instruction of young medical officers contributed materially to the success of the Navy's operations."

NAVY AWARDS AND COMMENDATIONS

Lieutenant Mark Walton Wolcott

Lieut. Mark Walton Wolcott, formerly of Philadelphia, was recently awarded the Air Medal "for meritorious achievement in aerial flight as crew member of an R4D transport plane attached to the South Pacific Air Transport command from July 15 to 25, 1943. When his craft was unable to land on the densely overgrown jungle terrain while transporting urgently needed supplies to our forces on New Georgia Island, Lieutenant Wolcott skillfully performed his duties and rendered invaluable assistance to his pilot in accurately dropping the cargo as the unarmed plane flew in at terrific speed and at tree top level to avoid intense enemy antiaircraft fire and aerial opposition, making several hazardous runs on the targets to complete the mission and frequently returning to base with-

out the protection of covering planes. Lieutenant Wolcott's cool courage and unwavering devotion to duty under extremely difficult conditions contributed materially to the success of these vital missions and were in keeping with the highest traditions of the United States Naval Service." Dr. Wolcott graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1941 and entered the service July 15, 1942.

Lieutenant Commander David Charles James

The Navy and Marine Corps Medal was recently awarded to Lieut. Comdr. David Charles James, formerly of East Cleveland, Ohio. The citation read "For heroic conduct as medical officer aboard the LST-396 when that ship with a cargo of gasoline and ammunition was attacked and sunk by enemy Japanese forces in the New Georgia Area on Aug. 18, 1943. Despite recurrent explosions and spreading flames, Lieutenant Commander (then Lieutenant) James disregarded imminent personal danger and entered a troop berthing compartment, under which the powder and gasoline had been stored, to save a helpless shipmate pinned under a mass of twisted wreckage. Bringing the severely injured man topside, he swiftly performed an emergency amputation in the midst of enveloping smoke and flames and then assisted in getting him over the side and into a life raft, where he applied a tourniquet and administered to the wounded comrade until rescued. Lieutenant Commander James's outstanding valor, his professional integrity and selfless devotion to duty were in keeping with the highest traditions of the United States Naval Service." Dr. James graduated from New York University College of Medicine, New York, in 1939 and entered the service July 14, 1941.

ARMY

NEW MEDICAL PLAN FOR AAF COMMANDS

A new program of industrial medicine and hygiene, developed by the medical staff of the Air Technical Service Command, will be installed in all AAF commands in the United States. The program, instituted by Col. J. M. Hargreaves, ATSC surgeon, is being taught and demonstrated to medical officers from other AAF commands in five twelve day seminars, which opened recently at five depots of the ATSC under a standardized plan developed by Colonel Hargreaves and Lieut. Col. Grover Sladczyk, chief, Industrial Hygiene Branch. One hundred leading medical officers from the AAF Training Command, the Second, Third and Fourth Air Forces and the Air Transport Command are attending the seminars conducted at Middletown, Pa., Ogden, Utah, Oklahoma City, San Antonio and Warner Robins, Ga. The program has been endorsed by the American Medical Association and the American College of Surgeons. Simultaneous conduct of the seminars was decided on, Colonel Hargreaves stated, in order to facilitate installation of the ATSC program in other commands as quickly as possible, following receipt of an order to that effect from Major Gen. David N. W. Grant, Air Surgeon, Washington, D. C. Lectures on more than fifty subjects will be followed by demonstrations and tours around each of the ATSC depots. On completion of the course the AAF medical officers will return to their respective commands to begin immediate installation of the ATSC program.

CONTROLLED RATION TEST COMPLETED

The most extensive controlled ration test ever conducted using U. S. military personnel was recently concluded with highly satisfactory results. Major William Beane of the Armored Medical Research Laboratory, Fort Knox, Kentucky, directed the test in cooperation with Major James Robinson, Inf., and Capt. David Bell of the Royal Canadian Medical Corps. American and Canadian expeditionary rations were used.

A battalion of American soldiers on maneuvers at an altitude of 8,850 feet above sea level in Colorado were fed exclusively on American rations C, K and 10 in 1 and Canadian Mess Tin B ration for a period of sixty days. During this time they were engaged in vigorous combat training. At the conclusion of the

test it was found that the troops were in better physical condition than at the start, with high morale. The rations were proved to be wholly adequate to sustain troops in vigorous combat. Certain items in the rations, however, were found less acceptable to the men than others, and these will be improved.

Four consultants in nutrition to the Surgeon General, Dr. Julian M. Ruffin, Dr. Frederick J. Stare, Dr. R. H. Kanpmeier and Dr. Virgil P. Sydenstricker, assisted in the physical examinations. Dr. Albert Mendeloff and Dr. Carleton B. Chapman of the Public Health Service also aided in the test. A unit from the Harvard Fatigue Laboratory under Dr. R. E. Johnson performed the laboratory examinations.

HONOR BRIGADIER GENERAL JAMES S. SIMMONS AT MARQUETTE UNIVERSITY

An honorary degree of Doctor of Science was recently bestowed on Brig. Gen. James S. Simmons, U. S. Army, at Marquette University School of Medicine, Milwaukee. Dr. Eben J. Carey, dean at the school, stated that "Brigadier General James Stevens Simmons, U. S. Army, doctor of medicine from the University of Pennsylvania in 1915, doctor of philosophy from George Washington University in 1934, doctor of public health from Harvard University in 1939, lecturer in preventive medicine and public health at Johns Hopkins, George Washington and Yale universities, member of the visiting committee for the Harvard University School of Public Health, chief and director of various army laboratories and schools from 1917 to 1940, chief, Preventive Medicine Service, Office of the Surgeon General, U. S. Army, since 1940, subchairman on the Lehman Committee, director of the Philippine Research Board of Manila from 1928 to 1930, president of the National Malaria Committee in 1942, member and fellow of many medical associations and committees, awarded the Sedgwick Memorial Medal in 1943, the medal of the Carlos J. Finley National Order of Merit in 1944, and for 'exceptionally meritorious services' in the United States of America Typhus Commission Medal in 1944, by his many distinct contributions to medical science, is entitled to the degree Doctor of Science, honoris causa." General Simmons was represented by Rev. Edward J. Drummond, S.J., Ph.D., dean of the Graduate School.

MEDICAL ADMINISTRATIVE CORPS OFFICERS

In order to relieve the critical shortage of doctors, the Medical Department recently increased its quota for admission to officer candidate schools and is continuing a program of training graduate administrative officers as battalion surgeon assistants. From now until April 1945 appointments will be made in the Medical Administrative Corps after seventeen weeks' training at Camp Barkeley, Texas, and Carlisle Barracks, Pa. From among those graduates, officers with appropriate backgrounds will be selected to receive six weeks' additional training at Camp Barkeley for duty assisting battalion surgeons.

The special training consists principally of advanced first aid which will qualify officers to relieve battalion surgeons of details and thus free the surgeons' time for purely medical and surgical work.

The thirty-second class of the Camp Barkeley Medical Administrative Corps Officer Candidate School graduated September 20. At the present time there are four other classes in various stages of the seventeen weeks instruction. Courses of instruction at the school include medical administration, supply, organization of the army, sanitation, first aid, chemical warfare, tactics, training and logistics. Brig. Gen. Roy C. Heflebower is commandant of the school.

MISCELLANEOUS

POSTWAR MEDICAL SERVICE COMMITTEE'S QUESTIONNAIRES

At the request of the Committee on Postwar Medical Service, questionnaires designed to gather information that would be useful for postwar planning were distributed by the Surgeons General of the Army, Navy and Public Health Service to each medical officer on active duty. Letters have been received from a number of medical officers indicating that they did not receive a questionnaire. In the event any medical officer did not receive a Postwar Planning Questionnaire, it is suggested that he write to the Committee on Postwar Medical Service, 535 North Dearborn Street, Chicago 10, and request one.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Camp McCoy, Wisconsin: Psychiatry, Psychoneurosis, Neurocirculatory Asthenia and Malingering, Dr. Lloyd H. Ziegler, November 1.

U. S. Naval Hospital, Santa Margarita Ranch, Oceanside, Calif.: Audiovisual Kinesthetic Methods in the Rehabilitation of the War Deafened, Lucelia M. Moore, October 16.

Truax Field, Wisconsin: Peptic Ulcer and Gastritis, Dr. Carl W. Eberbach, November 1.

U. S. Naval Hospital, Long Beach, Calif.: Some Aspects of the Treatment of Peptic Ulcer, Dr. William C. Boeck, October 21.

An extensive lecture tour of the various military hospitals in Kentucky and Tennessee will be made by Dr. Louis A. Buie of the Mayo Clinic under the auspices of the Wartime Graduate Medical Meetings. His topics for discussion will be "Anal Abscess and Fistula," "Anal Fissure, Hemorrhoids and Stricture," "Pilonidal Disease" and "Lesions of the Terminal Portion of the Colon." The schedule to be followed is Nichols General Hospital on the 9th of October, Fort Knox on the 10th, Camp Breckenridge on the 11th, Camp Campbell on the 12th, Nashville Army Air Center on the 13th, Camp Forrest on the 14th, Thayer General Hospital on the 16th, Kennedy General Hospital on the 17th and Dyersburg Station Hospital on the 18th.

NURSING IN THE UNITED STATES PUBLIC HEALTH SERVICE

Katharine S. Read, superintendent of nurses, United States Public Health Service, in supplement 176 to *Public Health Reports*, gives an outline of the service since it was established in 1798 by act of Congress as the Marine Hospital Service. That name was used for more than a century, or until 1902, when it was changed to the Public Health and Marine Hospital Service and in 1912 was changed to its present name.

For many years the duty of caring for American merchant seamen was the sole function of the Marine Hospital Service,

and nursing in the marine hospitals was done largely by male nurses. In 1918 the Surgeon General of the Public Health Service requested the American Red Cross to detail a nurse to survey the marine hospitals for the purpose of making a report on the nursing situation. Miss Lucy Minnigerode was assigned to make this survey. The Surgeon General was so impressed with her report that he recommended that she be appointed superintendent of nurses of the U. S. P. H. S. This was effective in 1919. On March 3, 1919 the Public Health Service was authorized to furnish medical service to veterans.

Since Pearl Harbor the Public Health Service has expanded greatly. The increase in the Coast Guard and the activities of the War Shipping Administration have developed an entirely new activity. Nurses have been assigned to act as instructors in nursing arts at the Pharmacist's Mates School of War Shipping Administration, Sheepshead Bay, Brooklyn. This school takes in a class of fifty trainees each week for a course of three months.

The functions of the nursing service are to provide nursing care to all service beneficiaries in the hospitals and dispensaries of the service and related projects and to instruct trainees of the Maritime Service and the Coast Guard in nursing arts both in the pharmacist's mates school and in the hospital wards.

Those entitled to hospital care by the Public Health Service include seamen, Coast Guard, Coast and Geodetic Survey: officers, ships' officers, and crews of coast and geodetic survey vessels; persons with leprosy, U. S. Employees' Compensation Commission beneficiaries, Public Health Service officers and employees (quarantine and field), immigration and naturalization service (persons detained under immigration laws and regulation), special study cases and pay patients.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, October 7, page 374)

MASSACHUSETTS

Boston City Hospital, Boston. Capacity, 2,537; admissions, 40,314. Dr. James W. Manary, Medical Director and Superintendent (2 residents—dermatology and syphilology).

NEW YORK

Cumberland Hospital, Brooklyn. Capacity, 400; admissions, 6,205. Dr. Max Seide, Medical Superintendent (14 interns, July 1, 1945). St. John's Long Island City Hospital, Long Island City. Capacity, 284; admissions, 5,418. Sister Thomas Francis, Superintendent (interns). Genesee Hospital, Rochester. Capacity, 256; admissions, 5,981. Dr. Leslie H. Wright, Superintendent (resident—medicine). St. John's Riverside Hospital, Yonkers. Capacity, 220; admissions, 4,398. Dr. John W. Pangburn, Chairman, Intern Committee (interns).

OHIO

Longview Hospital, Cincinnati. Capacity, 2,827; admissions, 482. Dr. E. A. Baber, Superintendent (3 residents—psychiatry).

ORGANIZATION SECTION

MEDICAL CARE IN A NATIONAL HEALTH PROGRAM

*The following amended report was adopted by the Governing Council of
The American Public Health Association
at its annual meeting, held in New York on October 4:*

A. THE NEEDS

I. A large portion of the population receives insufficient and inadequate medical care, chiefly because persons are unable to pay the costs of services on an individual payment basis when they are needed, or because the services are not available.

II. There are extensive deficiencies in the physical facilities needed to provide reasonably adequate services. Such facilities include hospitals, health centers and laboratories. The needs are most acute in poor communities, in rural areas and in urban areas where the population has increased rapidly or where the development of facilities has been haphazard or the financial support inadequate.

III. There are extensive deficiencies in the numbers and the distribution of personnel needed to provide the services. Here again the needs vary according to types of personnel and to types of communities.

IV. There are extensive deficiencies in the number and types of personnel qualified to administer facilities and services.

V. Many communities still are not served by public health departments; others inadequately maintain such departments. Thus, some communities have never utilized organized health work to reduce the burden of illness and others share its benefits only in part. In these communities especially, people lack information on the benefits of modern medical care.

VI. Expansion of scientific research is urgently needed. Despite past and current scientific advances, knowledge as to the prevention, control or cure of many diseases is lacking.

Each of the six conditions defined above can be broken down into many component parts representing specific needs. In general, however, solutions of these broad problems require simultaneous attack on four fronts: namely, the distribution of costs, construction of facilities, training of personnel and expansion of knowledge.

B. THE OBJECTIVES

I. A national program for medical care should make available to the entire population all essential preventive, diagnostic and curative services.

II. Such a program should insure that the services provided be of the highest standard and that they be rendered under conditions satisfactory both to the public and to the professions.

III. Such a program should include the constant evaluation of practices and the extension of scientific knowledge.

C. RECOMMENDATIONS

The recommendations presented in this report represent guides to the formulation of a policy for action. It is believed that study of these recommendations by the professions and others concerned in the states and localities will produce new and more specific recommendations for the attainment of the objectives of a national health program.

Recommendation I. The Services

a. A national plan should aim to provide comprehensive services for all the people in all areas of the country. In light of present day knowledge, the services should include hospital care, the services of physicians (general practitioners and specialists), supplementary laboratory and diagnostic services, nursing care, essential dental services, and prescribed medicine and appliances. These details of content must remain subject to alteration according to changes in knowledge, practices and organization of services.

Because of inadequacies in personnel and facilities, this goal cannot be attained at once, but it should be attained within ten

years. At the outset, as many of the services as possible should be provided for the nation as a whole, having regard for resources in personnel and facilities in local areas. The scope of service should then be extended as rapidly as possible, accelerated by provisions to insure the training of needed personnel and the development of facilities and organization.

b. It is imperative that the plan include and emphasize the provision of preventive services for the whole population. Such services include maternity and child hygiene, school health services, control of communicable diseases, special provisions for tuberculosis, venereal diseases and other preventable diseases, laboratory diagnosis, nutrition, health education, vital records and other accepted functions of public health agencies, which are now provided for a part of the population.

c. Insofar as may be consistent with the requirements of a national plan, states and communities should have wide latitude in adapting their services and methods of administration to local needs and conditions.

Recommendation II. Financing the Services

a. Services should be adequately and securely financed through social insurance supplemented by general taxation, or by general taxation alone. Financing through social insurance alone would result in the exclusion of certain economic groups and might possibly exclude certain occupational segments of the population.

b. The services should be financed on a nationwide basis in accordance with ability to pay, with federal and state participation and under conditions which will permit the federal government to equalize the burdens of cost among the states.

Recommendation III. Organization and Administration of Services

a. A single responsible agency is a fundamental requisite to effective administration at all levels—federal, state and local. The public health agencies—federal, state and local—should carry major responsibilities in administering the health services of the future. Because of administrative experience and accustomed responsibility for a public trust, they are uniquely fitted among public agencies to assume larger responsibilities and to discharge their duties to the public with integrity and skill. The existing public health agencies, as now constituted, may not be ready and may not be suitably constituted and organized, in all cases, to assume all of the administrative tasks implicit in an expanded national health service. Public health officials, however, should be planning to discharge these larger responsibilities and should be training themselves and their staffs. This preparation should be undertaken now because, when the public comes to consider where administrative responsibilities shall be lodged, it will be influenced in large measure by the readiness for such duties displayed by public health officers and by the initiative they have taken in fitting themselves for the task.

b. The agency authorized to administer such a program should have the advice and counsel of a body representing the professions, other sources of services and the recipients of services.

c. Private practitioners in each local administrative area should be paid according to the method they prefer, i. e., fee-for-service, capitation, salary or any combination of these. None of the methods is perfect; but attention is called to the fact that fee-for-service alone is not well adapted to a system of wide coverage.

d. The principle of free choice should be preserved to the population and the professions.

e. State departments of health and other health agencies are urged to initiate studies to determine the logical and practical administrative areas for a national medical care plan.

Recommendation IV. Physical Facilities

a. Preceding, or accompanying, the development of a plan to finance and administer services, a program should be developed for the construction of needed hospitals, health centers and related facilities, including modernization and expansion of existing structures. This program should be based on federal aid to the states and allow for participation by voluntary as well as public agencies, with suitable controls to insure the economical and communitywide use of public funds. The desirability of combining hospital facilities with the housing of physicians' offices, clinics and health departments should be stressed.

b. Federal aid to the states should be given on a variable matching basis in accordance with the economic status of each state.

c. Because of its record of experience and accomplishment in this field, the U. S. Public Health Service should administer the construction program at the federal level, in cooperation with the federal agencies responsible for health services and construction.

d. Funds available under this program should be granted only if:

(1) The state administrative agency has surveyed the needs of the state for hospitals, health centers and related facilities and has drawn up a master plan for the development of the needed facilities (taking account of facilities in adjacent states); or, in the absence of a state plan, the project is consistent with surveys of construction needs made by the U. S. Public Health Service;

(2) The proposed individual project is consistent with the master plan for the state; its architectural and engineering plans and specifications have been approved by the state agency and/or the U. S. Public Health Service, and there is reasonable assurance of support and maintenance of the project, in accordance with adequate standards.

e. State health departments are urged to conduct studies to develop state plans for the construction of needed hospitals, health centers and related facilities. Such studies should be made in cooperation with official health agencies, with state hospital associations and other groups having special knowledge or interests.

Recommendation V. Coordination and Organization of Official Health Agencies

a. The activities of the multiple national, state and local health agencies should be coordinated with the services provided by a national program. There is no functional or administrative justification for dividing human beings or illnesses into many categories to be dealt with by numerous independent administrations. It is difficult to reorganize agencies or to combine activities, and this cannot be accomplished hurriedly. Therefore, studies and conferences should be undertaken without delay at the federal level and in those states and communities where the health structure is already unnecessarily complex.

b. The federal and state governments should provide increased grants for the extension of adequate public health organization to all areas in all states. Increased federal grants should be made conditional upon the requirement that public health services of at least a specified minimum content shall be available in all areas of the state.

Recommendation VI. Training and Distribution of Service Personnel

a. Within the resources of the program, financial provisions should be made to assist qualified professional and technical personnel in obtaining postgraduate education and training.

b. The plan should provide for the study of more effective use of auxiliary personnel (such as dental hygienists, nursing aides and technicians) and should furnish financial assistance for their training and utilization.

c. Professional and financial stimuli should be devised to encourage physicians, dentists, nurses and others to practice in rural areas. Plans to encourage the rational distribution of personnel, especially physicians, should be developed as quickly as possible in view of the coming demobilization of the armed forces. Such plans should be integrated with the whole scheme of services and the establishment of more adequate physical facilities.

Recommendation VII. Education and Training of Administrative Personnel

a. Education and training of administrative personnel should be encouraged, financially and technically, especially for those who may serve as administrators of the medical care program, for hospital and health center administrators and for nursing supervisors.

b. State health departments should utilize training funds that are now available to train personnel in such technics as administration of health and medical services, and hospitals. Such a training program may contribute more than any other single activity to the future role of the official public health agency. As a corollary, the attention of schools of public health is directed to the importance of establishing the necessary training courses.

Recommendation VIII. Expansion of Research

a. Increased funds should be made available to the U. S. Public Health Service, to other agencies of government (federal, state and local) and for grants-in-aid to nonprofit institutions for basic laboratory and clinical research and for administrative studies and demonstrations designed to improve the quality and lessen the cost of services.

b. The research agencies and those responsible for making grants-in-aid should be assisted by competent professional advisory bodies to insure the wise and efficient use of public funds.

The American Public Health Association through its national organization and its constituent societies stands ready to collaborate with the various professional bodies and civic organizations who may be concerned with either the provision or receipt of medical service with a view to implementing the foregoing general principles.

WASHINGTON LETTER

(From a Special Correspondent)

Oct. 9, 1944.

Honorary Consultants of the Army Medical Library

Sixty physicians who met here on October 5 and 6 to organize the honorary consultants of the Army Medical Library heard Archibald MacLeish, librarian of Congress, describe the projected Holmes Memorial and the location, nearby, of the new Army Medical Library Building, to be built after the war. Plans are by Eggers and Higgins, architects of the National Gallery of Art and the Thomas Jefferson Memorial. Col. Harold W. Jones, M. C., director, presided, and Major Gen. George F. Lull greeted consultants for the Surgeon General. Colonel Jones said that one of the difficult tasks was recruiting adequate personnel, as the library, because of special requirements, could

not find suitable staff under Civil Service recruiting. Miss Mary Louise Marshall of the committee on new classification, Wyllis Wright, cataloging consultant, Major Thomas E. Keys, Sn. C., and Dr. Max Fisch of the Cleveland branch discussed technical aspects. Keyes D. Metcalf, director of the Harvard University libraries, described the recent survey and Dr. Thomas S. Cullen reviewed legislation.

Dr. O. H. Perry Pepper was toastmaster at a dinner in the Statler Hotel, at which Dr. Morris Fishbein, Editor of *THE JOURNAL*, said that, in view of the necessity "of making the library a living bibliographical force for medical research," private funds might be obtained to supplement the regular appropriation from Congress. Dr. Reginald Fitz of Harvard University discussed the history of medicine, with special reference to the book by Henry I. Bowditch, published in 1800.

Dr. John F. Fulton, professor of physiology and librarian of the Historical Library at the Yale School of Medicine, was elected president of the honorary consultant group, Dr. Chauncey D. Leake, vice president and dean of the University of Texas School of Medicine, vice president, Colonel Jones secretary-treasurer and Dr. Clyde L. Cummer of Cleveland, Dr. Wilburt C. Davison, dean of the School of Medicine of Duke University, Dr. Henry R. Viets, librarian of the Boston Medical Library and Dr. Morris Fishbein Executive Committee members.

American Medicine Aware of Its Responsibility

Optimism for the future of medicine in the United States was expressed by Dr. John H. Fitzgibbon of Portland, Ore., chairman of the Council on Medical Service and Public Relations of the American Medical Association, at the sixteenth annual scientific assembly of the District of Columbia Medical Society. He expressed his confidence in the "sincerity and unselfishness of the medical profession and their adaptability to any situation." American medicine, he said, is "the best in the world today," which, he said, American doctors took pride "in maintaining at its high level while at the same time recognizing and admitting its inadequacies." The medical profession, he said, is cognizant of the evil effects on a community and nation of ill health, poor housing, malnutrition, congestion, economic insecurity, unemployment, lack of cultural development, intolerance and moral imperfection. "Correction of all these evils is our responsibility as citizens, but the solution of health problems is our own special responsibility as medical citizens."

Expanding in detail on the objective of the American Medical Association, as reaffirmed by the House of Delegates in June

1944, namely "availability of medical care of a high quality to every person in the United States," Dr. Fitzgibbon added "I recognize that there will be a minority disagreement by those advocating complete socialization and government control of medicine and allied activities. Those who believe in compulsion have their arguments, which I am willing to listen to as a private practitioner and part time teacher. I cannot agree with them. I cannot agree that the private practitioner has been relegated to the position of distributor of medical service or that the full time salaried man is alone God's gift to humanity. No doubt much can be said on both sides, but further argument merely adds to the medical windstorm." The National Program for Physical Fitness, outlined by Col. Leonard G. Rowntree, will, he said, enable America, "which is predestined to play a major role in world leadership," to make her people physically, mentally and morally fit.

Accelerating the "production" of doctors by "getting boys and girls into college two years earlier by cutting out the overlapping between high school and college" was advocated by William Mather Lewis, president of Lafayette College, in an address which concluded the three day session. He criticized the "deferred maturity" of doctors at the age of 31 and expressed the belief that they could complete education much earlier "at least during the transition period" between war and peace.

Among the other speakers were Major Gen. Norman T. Kirk, Army Surgeon General; Vice Admiral Ross T. McIntyre, Navy Surgeon General; Major Gen. David N. W. Grant, Air Surgeon, and Commodore Arthur W. Clarke, D.S.O., Royal Navy, chief of staff to Admiral Sir Percy Noble of the British navy delegation to the United States.

MEDICAL ECONOMIC ABSTRACTS

OHIO MEDICAL CARE PLAN

The Academy of Medicine of Cincinnati has endorsed a plan by which a mutual insurance company in cooperation with the Blue Cross Plan of Ohio will undertake to provide surgical and obstetric service for members of the Blue Cross Plan.

In a statement which accompanies the issue of the Monthly News Letter of the Academy of Medicine for August 12 it is stated that the plan proposes to include the following benefits for subscribers:

1. The benefits to be paid the subscriber for surgical and obstetric care not to be lower than the highest provided by commercial insurance carriers nor lower than the scale of fees, where applicable, paid by the industrial commission to physicians.
2. Full coverage for dependent members of subscriber's family, which now is not available through commercial insurance carriers.
3. All types of surgical procedure covered and no exclusions except where such treatment is available without cost to the subscriber under existing laws.
4. No limitations except as follows:
 - (a) Hospitalized illnesses only.
 - (b) Waiting period of six months for tonsil and adenoid operations.
 - (c) Membership waiting period of nine months for obstetric benefits.
 - (d) Obstetric benefits available only on insured or insured's spouse.
 - (e) Waiting period of one year for preexisting conditions.
 - (f) Available only on group underwriting basis with requirement of 50 per cent enrollment of employees.
 - (g) Fees must be paid by employer or collected by him on payroll deduction basis from employee.
 - (h) \$150 limit for two or more operations within period of three months.

Payment is to be on the indemnity plan but sufficient to meet the usual charge made to wage earners. To organize such a mutual company a deposit of \$50,000 with the state insurance department is required, and another \$25,000 must be raised to pay the cost of the organization period.

UNITED MEDICAL SERVICE PLAN OF NEW YORK

According to a circular addressed "to the members of the Medical profession of Metropolitan New York in which the United Medical Service, Inc. will operate" this service is the result of a merger of Community Medical Care, Inc., and Medical Expense Fund of New York, Inc. It is the only company of this type in greater New York which has been approved by the Medical Society of the State of New York. The merger brings to the new organization approximately 6,500 members who have been subscribers to the previous organization.

The United Medical Service, Inc. "has adequate cash resources: its legal surplus as of July 1, 1944 was approximately \$144,000. It has medical contracts at present in force insuring over 56,000 persons." It is affiliated through the organization of the Associated Hospital Service, which now has 1,500,000 subscribers. Physicians' fees will be based on the workmen's compensation schedule, and in the beginning only a limited service contract covering obstetrics and surgical specialties in hospitals will be offered.

The income limits are to be determined by the board of directors and approved by the council of the Medical Society of the State of New York. It is proposed to issue comprehensive contracts for full medical service on an experimental basis limited in the beginning to not more than 25,000 subscribers.

Nathan B. Van Etten, M.D., is chairman of the board, and Rowland H. George president.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. Hubert S. Houston has resigned as tuberculosis physician at the Kilby Prison Hospital, Montgomery, to devote full time to his duties as resident physician at the Montgomery Tuberculosis Sanatorium.

Pediatric Meeting.—On September 26 the Alabama Pediatric Association held its eighteenth annual meeting in Birmingham. Among the speakers were:

Dr. Albert E. Casey, Birmingham, Human and Place Contacts and Radial Spread of Epidemic Poliomyelitis.
Dr. William Fred Mayes, Atlanta, Ga., The Premature Infant.
Dr. Ralph V. Platon, New Orleans, Kodachrome Clinic.
Dr. Roy R. Kracke, Birmingham, Diagnosis of Hemorrhagic Diseases in Children.
Dr. Hughes Kennedy Jr., Birmingham, The Rh Factor in Pediatrics.

New Medical School Receives Donation for Research.—A check for \$25,000 has been given to the new University of Alabama Medical School for use exclusively in research work. The gift was made possible under the will of John R. Irby, owner of the Shelby Springs properties. Newspaper reports indicated that Mr. Irby directed that the net proceeds from the sale of Shelby Springs be turned over to some medical school, to be selected by the executor, for use in research into the cause and cure of arthritis, from which he had suffered for many years. Sidney W. Smyer, Birmingham attorney, as executor, selected the Alabama medical school for the gift.

CALIFORNIA

Changes in Licensure.—At a meeting of the California State Board of Medical Examiners in Los Angeles in August the licenses to practice medicine were restored to Drs. Pearl J. Anderson and Paul S. Traxler.

Medical Society Completes Fifty Years.—The Santa Barbara County Medical Society, which was organized July 4, 1894 with the late Dr. James B. Shaw as president, is planning a program to commemorate the event sometime this year, it is reported.

Symposium on Heart Disease.—The fifteenth annual postgraduate symposium on heart disease of the San Francisco Heart Committee will be held October 26-28. The first day's session will be at the University of California Medical School and the second at the Stanford University School of Medicine and San Francisco Hospital. The third day's program will be held in the auditorium of the nurses' home, Mount Zion Hospital. Dr. Francis L. Chamberlain is chairman of the San Francisco Heart Committee of the San Francisco Tuberculosis Association.

Institute in Health Education.—Clair E. Turner, Dr. P.H., health education consultant of the Office of the Coordinator of Inter-American Affairs, will conduct an institute in health education for professional workers, October 17-18. At the first education for physicians, dentists, nurses and others the discussion will be devoted to community efforts in education for health. The second meeting will deal with the balancing of learning by experience against learning by instruction, individual health education and the doctor's and dentist's place in health education. The institute is being sponsored by the San Francisco County Medical Society and the health education committee of the San Francisco Community Chest.

ILLINOIS

Personal.—Dr. Edward K. Steinkopff, Janesville, Wis., has been appointed superintendent of the Madison County Sanatorium, Edwardsville, effective November 1, succeeding Dr. Joseph T. Maher. Dr. Steinkopff recently resigned his position as chief of the state division of tuberculosis control to accept a position as medical director of the Pinehurst Sanatorium, Janesville (THE JOURNAL, July 22, p. 858).

Dr. Kronenberg Joins Caterpillar Tractor Company.—Dr. Milton H. Kronenberg, Chicago, chief of the division of industrial hygiene of the Illinois Department of Public Health, has been appointed assistant to the medical director at Cater-

pillar Tractor Company, Peoria, effective October 1. Dr. Harold A. Vonachen, Peoria, is medical director. Dr. Silvio M. Scalzo, a member of the staff at the company since 1942, has been promoted to chief plant physician. Dr. Herman M. Soloway, who has been serving as venereal disease control officer in the state division of industrial hygiene (THE JOURNAL, July 22, p. 858) will be acting chief until a successor to Dr. Kronenberg has been named.

Chicago

University News.—Dr. Malcolm T. MacEachern, associate director of the American College of Surgeons, lectured at the University of Chicago School of Medicine, September 27, under the auspices of the Nu chapter of Alpha Kappa Kappa. His subject was "Postgraduate Medical Education."

Affirm Jail Term for Dr. Fernel.—The circuit court of appeals on October 3 affirmed the sentence of one year in prison and a fine of \$500 given a year ago by Judge Philip L. Sullivan to Dr. Jean Paul Fernel (THE JOURNAL, Nov. 27, 1943, p. 849) for using the mails to defraud, newspapers report. It was also reported that Dr. Fernel has been in the county jail for the past several weeks because of inability to post a \$5,000 bond on new government fraud charges.

KANSAS

Thirty Years' Service on State Board Honored.—Dr. Harry L. Aldrich, Caney, was guest of honor at a luncheon given by the Kansas State Board of Health recently in recognition of his thirty years of service as a member of the board. A plaque was presented to Dr. Aldrich bearing the following inscription:

In recognition of thirty years of service as a member of the Kansas State Board of Health, and as a memento of his valuable contribution to the work of maintaining and promoting the public health of our great state of Kansas for nearly a third of a century, this plaque is dedicated by his colleagues.

Medical Education Fund.—To provide refresher courses and graduate training for physicians of the state, the executive council of the Kansas Medical Society has authorized the establishment of a fund to finance the work. A goal of \$100,000 has been set. The plan proposed a series of short, intensive courses to be offered by the University of Kansas School of Medicine, Lawrence-Kansas City, with classes starting early in 1945 and with the state medical society and the state board of health cooperating. The main purpose of the funds are to:

Provide immediate assistance to returning Kansas physicians now in military service, through refresher courses covering all fields of medicine.
Rehabilitate those wounded or suffering other service incapacities by training in specialties adapted to their disabilities.
Provide a revolving medical scholarship for children of Kansas physicians losing their lives in service in the present war who have been accepted as students in any approved medical college.
Provide a permanent program of postgraduate training in medicine and surgery for all Kansas physicians.

Postgraduate courses will be conducted on a circuit basis in forty-five or fifty centers of the state to supplement the short postgraduate courses that will continue to be given in various towns in the state. According to the *News Letter* of the Kansas State Board of Health the Kansas Medical Society formulated the plan especially in recognition of the sacrifices so willingly made by members now serving in the armed forces.

MARYLAND

Course in Industrial Medicine.—The John Hopkins School of Hygiene and Public Health will conduct a course in industrial health for eight weeks beginning October 17. The program will include a comprehensive range of industrial health phases.

MINNESOTA

Personal.—Dr. Walter Henry Judd, Minneapolis, representative in Congress from the fifth district of Minnesota, received the honorary degree of doctor of laws from Washington and Jefferson College, Washington, Pa., recently.

Pediatric Meeting.—The Northwest Pediatric Society held its fall meeting at the White Pine Inn, Bayport, September 29-30. The guest speaker was Dr. Arild E. Hansen, Galveston, who discussed "Problems of Lipid Metabolism in Pediatrics."

Dr. Rosenow Goes to California.—Dr. Edward C. Rosenow, who recently became emeritus professor of experimental bacteriology at the Mayo Foundation, University of Minnesota Graduate School, has accepted an invitation to join the

California Institute of Technology, Pasadena, to continue with his research. Dr. Rosenow graduated at Rush Medical College in 1902 and has been identified with the Mayo Clinic and University of Minnesota since 1915.

MISSISSIPPI

Changes in Health Personnel.—Dr. Barbara Hunt, Meridian, has been appointed health officer of Chickasaw County. Dr. Robert E. Rothermel has been appointed director of the Harrison County Health Department, succeeding Dr. Henry W. Kassel, who has been assigned to a position in Guatemala City, Guatemala. Dr. Robert H. Bostwick Jr. has resigned as health officer of Marshall and Union counties, New Albany; he will enter private practice in New Albany.

Dr. Underwood Honored.—The *Mississippi Doctor* for September has been designated the Underwood issue in honor of Dr. Felix J. Underwood, state health officer. Dr. Underwood is past president of the American Public Health Association. The journal carries many tributes for Dr. Underwood and a review of the health of the state under his direction. Among contributors are Thomas Parran, Surgeon General of the U. S. Public Health Service, Dr. John A. Ferrell, medical director of the John and Mary R. Markle Foundation, New York, and Dr. Waller S. Leathers, dean of the Vanderbilt University School of Medicine, Nashville, Tenn., and the immediate predecessor in Mississippi of Dr. Underwood.

MISSOURI

New Director of Child Hygiene.—Dr. Lynn M. Garner, formerly health officer of district number 8 with headquarters at Higginsville, has been appointed director of the division of child hygiene for the state board of health, Jefferson City. Dr. Garner graduated at St. Louis University School of Medicine in 1930.

Medical Committee for Vocational Education.—Dr. Robert Elman, St. Louis, has been appointed chairman of a committee which was recently appointed to work with the state board of vocational education in extending the state's rehabilitation program. The program, which was made possible by legislation in 1943, aims to assist the indigent disabled to full or increased earning capacity. Other members of the committee include Drs. Frank R. Bradley, J. Arthur O'Reilly, James B. Costen, Edwin F. Gildea, St. Louis; B. Landis Elliott, Frank D. Dickson, Herbert L. Mantz, A. Graham Ashler, Kansas City; Arthur R. McComas, Sturgeon; William A. Bloom, Fayette; C. B. Souter Smith, Springfield; Dudley S. Conley, Columbia, and John W. Williams Jr., Jefferson City.

Health Plan Soon in Operation.—With the granting of a pro forma decree of incorporation to Missouri Medical Service, plans are near completion to start the state's prepayment medical and surgical care plan approved this year by the Missouri State Medical Association (*THE JOURNAL*, July 22, p. 859). The October state medical journal expected the plan to be in operation within six weeks. The plan will be administered through Blue Cross Service under authorization of the board of trustees of Missouri Medical Service, which will guide policies. It provides for medical and surgical care for hospitalized cases at a cost to single persons of 85 cents per month and to families, regardless of their size, of \$2.25 per month. Although subscribers must join in groups, professional or trade association, labor unions or others, the plan is open to every one. For the present, families will be limited to \$1,000 of medical and surgical care in one year.

NEBRASKA

Mid-West Clinical Society.—The twelfth annual session of the Omaha Mid-West Clinical Society will be held at the Hotel Paxton, Omaha, October 23-27, under the presidency of Dr. James F. Kelly, Omaha. Among the speakers will be:

- Dr. Leroy Sante, St. Louis, Correlation of the Roentgenologic and Pathologic Findings in Acute Pneumonic Processes.
- Dr. Thomas P. Findley Jr., New Orleans, The Symptomatology of Chronic Anemia and Shigellosis.
- Dr. Clarence Guy Lane, Boston, The Cutaneous Disturbances Caused by Therapeutic Measures.
- Lieut. Col. James Barrett Brown, M. C., Compound Facial Injuries.
- Major Albert B. Sabin, M. C., Natural History of Human Poliomyelitis.
- Dr. Edward H. Rucarcson, Rochester, Minn., Real versus Supposed Disturbances of the Endocrine Glands.
- Dr. Clifford B. Lull, Philadelphia, Diet in Pregnancy.
- Dr. Paul H. Hohnker, Chicago, Post-Thyroidectomy Bilateral Laryngeal Paralysis: Medical and Surgical Aspects.
- Dr. Alton R. Kilgore, San Francisco, The Changing Picture of Breast Cancer.

Dr. Nolan D. C. Lewis, New York, Psychosomatic Medicine.
Dr. Carl E. Badgley, Ann Arbor, Mich., Pain in the Upper Extremity. Differential Diagnosis and Treatment.
Dr. Malcolm T. MacEachern, Chicago, The American College of Surgeons' Program for the Expansion of Graduate Training in Surgery.
Edward R. Loveland, executive secretary, American College of Physicians, Philadelphia (subject not announced).

There will be symposiums on "Place of X-Ray and Radioactive Substances in the Treatment of Disease," "Acute Upper Respiratory Infections" and "Diabetes." In addition a series of lecture courses and round table discussions will be held during the meeting covering a wide range of subjects. The program will also include a number of clinics. Thursday evening has been designated the Omaha Douglas County Medical Society Night with the following speakers: Dr. Badgley on "Present Day Concept of the Treatment of Acute Hematogenous Osteomyelitis" and Dr. Lewis, "Recent Trends in Neuropsychiatric Thinking and Practice." Friday morning will be devoted to a discussion of military medicine with the following speakers:

- Lieut. Col. Vernon L. Hart, M. C., A Study of One Hundred Fractured Legs.
- Col. John B. Grow, M. C., Bronchiectasis, Its Surgical Treatment.
- Major Frank P. Foster, M. C., Rheumatic Fever Clinical Findings, Comment on Diagnostic and Therapeutic Features from 350 Cases.
- Major Charles R. McAdam, M. C., Meningococcal Infections.
- Lieut. Col. Frank B. Queen, M. C., Clinical Uses of Penicillin, with Reasons for Therapeutic Failures.

NEW YORK

Personal.—Dr. Charles R. Seymour, Binghamton, was given a citation for distinguished service by the Alumni Association of Albany Medical College, September 16. Dr. Seymour graduated at Albany in 1892 and has served twice as president of the Broome County Medical Society. Dr. Walter W. Wicks, Pine Plains, was recently appointed township health officer, succeeding the late Dr. Ellwood Oliver.

Rest Center for Merchant Seamen.—The seventh rest center in the United States to care for the merchant seamen was dedicated September 28 when the 72 acre estate of the late Mrs. Christian R. Holmes, the Chimneys, Sands Point, L. I., was turned over to the United Seamen's Service and the War Shipping Administration, which will jointly operate the place for the benefit of seamen who suffer from convoy fatigue or enemy action, according to the *New York Times*. Dr. Daniel Blain, New York, is medical director. The dedication also marked the second anniversary of the USS-WSA medical division. Among the speakers at the dedication was Ralph C. Williams, assistant surgeon general of the U. S. Public Health Service.

New York City

Harvey Lecture.—E. Newton Harvey, Ph.D., Henry Fairfield Osborn professor of physiology, Princeton University, N. J., will deliver the first Harvey Society Lecture October 26 on "Decompression Sickness and Bubble Formation in Blood and Tissues." The lecture is one of a series given annually by the Harvey Society in affiliation with the New York Academy of Medicine.

Friday Afternoon Lectures.—On November 3 the regular Friday afternoon lectures of the New York Academy of Medicine will open for the current season with a talk by Dr. James A. Shannon on "Recent Advances in Drug Therapy." The lectures for the remainder of 1944 include:

- Lieut. Col. Theodore C. Thompson, M. C., War Fractures, November 10.
- Dr. Joseph Harkavy, Newer Concepts of Bronchial Asthma and Treatment, November 17.
- Dr. Frank L. Melency, The Problem of Infection in Burns, December 1.
- Dr. Emanuel Libman, Diagnostic Observations on Abdominal Diseases, December 8.
- Dr. Arthur M. Fishberg, The Surgical Treatment and Course of Essential Hypertension, December 15.

Suiter Lectureship Created.—Dr. Stuart Mudd, professor of bacteriology, University of Pennsylvania School of Medicine, Philadelphia, will deliver the newly created A. Walter Suiter Lecture, November 2, on "Air Borne Infection: The Rationale and Means of Disinfection of Air." The lecture was created under the will of the late Dr. A. Walter Suiter, Herkimer, N. Y., and will be conducted annually under the auspices of the committee on public health relations of the New York Academy of Medicine. Dr. Suiter, who graduated at the Medical Department of Columbia College, New York, in 1871, died May 28, 1925, aged 75. He served for a long time as coroner of Herkimer County and as medical examiner for a number of insurance groups. He aided in the establishment of the state board of medical examiners. He was vice president of the state medical society in 1888, president in 1891, held at various times other positions of importance and was considered a pioneer in the development of legal medicine.

PENNSYLVANIA

Society News.—Dr. Lewis R. Wolf, Philadelphia, discussed the "Surgical Treatment of Strabismus" before the Reading Eye, Ear, Nose and Throat Society in Reading, September 20.

—Dr. Ross K. Childerhose, Harrisburg, was elected president of the Pennsylvania chapter of the American College of Chest Physicians at its recent annual meeting in Pittsburgh. Dr. Chevalier L. Jackson, Philadelphia, is vice president and Dr. Edward Lebovitz, Pittsburgh, secretary-treasurer.

—Dr. Charles H. Mann Jr., New York, discussed "Recent Developments in Diagnosis and Control of Venereal Disease" before the Harrisburg Academy of Medicine, September 19.

Philadelphia

Dr. Bertolet Named Coroner.—Dr. J. Allan Bertolet has been appointed coroner of Philadelphia to succeed the late Dr. Herbert M. Goddard. Dr. Bertolet graduated at the Jefferson Medical College of Philadelphia in 1916.

University News.—Among the speakers at the annual alumni dinner of the Jefferson Medical College of Philadelphia September 21 were Dr. William H. Perkins, dean of the medical college, who graduated in 1917, Major Gen. George F. Lull, M. C., class of 1909, and Dr. John Lincoln Bower, class of 1888, who represented the "old guard." Sixteen members of this year's graduating class received commissions as lieutenant (jg) medical corps, U. S. Naval Reserve, 109 members temporary commissions as first lieutenant, medical corps, Army of the United States, and two members commissions as first lieutenant, Army Medical Reserve Corps. Franklyn B. Snyder, LL.D., president of Northwestern University, Evanston, Ill., gave the 120th annual commencement address September 22 on "An Incident in the History of Fort Ticonderoga." The September graduating class recently presented to the college a portrait of Dr. Charles E. G. Shannon, professor of ophthalmology since 1927.

Graduate Medical School to Include Dentistry.—The Graduate School of Medicine of the University of Pennsylvania, organized in 1916 to provide for graduate studies in clinical medicine, will in the future extend its activities to include graduate studies in dentistry. The new work will be under the direction of John W. Ross, D.D.S., who has been appointed vice dean for dentistry in the graduate school of medicine and who will work in cooperation with the vice deans for other medical studies under Dr. Robin C. Buerki, dean of the Graduate School of Medicine. In connection with the new graduate program in dentistry, courses are being planned for graduate studies in oral surgery, orthodontics, prosthetics and oral medicine-periodontics. The first period of study for those students entering the graduate program will be devoted to basic studies involving the medical sciences as applied to the clinical specialties concerned, together with the principles and practice of that specialty and its relation to other clinical specialties. The studies of this period will lead to a certificate. The second period of study will be under preceptors, and this period must be preceded by the basic studies at the university. The studies under the preceptors may be carried on at any approved institution, and academic credit will be granted for time by the university, provided the specific plan for such studies for each candidate receives due approval and acceptance by the university. The successful completion of the period of study carried on under the preceptors will lead to the degree of master of science in dentistry. The program in dentistry in the Graduate School of Medicine will be independent of the School of Dentistry at the university. Dr. Ross graduated at the School of Dentistry at the University of Pennsylvania in 1917.

RHODE ISLAND

Medical Convocation.—Brown University, Providence, sponsored a medical convocation recently with Dr. Charles A. McDonald, chairman of the newly created department of medical sciences, presiding. James P. Adams, LL.D., vice president of the university, opened the meeting with a talk on "Department of Medical Sciences in Brown University," to which Dr. Elihu S. Wing, Providence, president of the Rhode Island Medical Society, responded. The convocation address was delivered by Dr. Henry R. Viets, librarian of the Boston Medical Library, on "Medical Education—Old Purposes and New Methods." The new department was announced in THE JOURNAL, July 22, page 861.

State Journal Honors Hospital on Centennial.—The Rhode Island Medical Journal for August was designated the Butler Hospital Centennial Issue. The journal carried historical material on the hospital reviewing its progress in the last hundred years. The hospital was created with a bequest of \$30,000 left by Nicholas Brown in 1841 "toward the erection or endowment of a . . . retreat for the insane." After the original charter was granted to establish the Rhode Island Asylum for the Insane the Hon. Cyrus Butler gave \$40,000 toward the institution, provided a contingent gift could be subscribed. In November 1844 the institution was named the Butler Hospital for the Insane. Butler Hospital was not only the first mental hospital but the first hospital in Rhode Island.

TEXAS

Change in Health Officers.—Dr. William P. Scarlett, director of the division of venereal diseases in the Corpus Christi Health Department, has been appointed in charge of the Wichita County Health Unit, succeeding Dr. David F. Bradley, who has been appointed medical officer in charge of the state quarantine hospital, Corpus Christi.

State University Considers Move.—In a recent report to the board of regents of the University of Texas, Homer P. Rainey, LL.D., president of the university, made the recommendation that the medical branch be moved from Galveston to Austin to be merged with the main university. The recommendation has evoked considerable discussion in newspapers and other sources but no definite action has been taken.

New Experimental Society.—Dr. James A. Greene, Houston, was recently elected chairman of the newly organized Southwest Section for the Society of Experimental Biology and Medicine and Dr. Donald H. Slaughter, Dallas, was elected secretary. Meetings of the new group will be held three times a year in rotation at Southwestern Medical College, Dallas, Baylor University College of Medicine, Houston, University of Texas, Austin, and occasionally at the University of Oklahoma School of Medicine, Oklahoma City.

Dallas Clinical Conference.—The Dallas Southern Clinical Society will hold its fifteenth annual spring clinical conference at the Hotel Adolphus, Dallas, March 19-22, with the following speakers:

Dr. J. Arnold Barger, Rochester, Minn., gastroenterology.
Dr. Charles A. Doan, Columbus, Ohio, internal medicine.
Dr. Samuel C. Harvey, New Haven, Conn., surgery.
Dr. Charles B. Huggins, Chicago, urology.
Dr. Ira H. Lockwood, Kansas City, Mo., radiology.
Dr. Donovan J. McCune, New York, pediatrics.
Dr. Joe V. Meigs, Boston, gynecology.
Dr. Leroy A. Schall, Boston, otolaryngology.
Dr. William H. Sebrell Jr., Bethesda, Md., basic science.
Dr. Edmund B. Spaeth, Philadelphia, ophthalmology.
Dr. Richard H. Sweet, Boston, surgery.
Dr. George W. Thorn, Boston, internal medicine.

VIRGINIA

Dr. Wampler Goes to Baltimore.—Dr. Frederick J. Wampler has resigned as professor of preventive and industrial medicine at the Medical College of Virginia, Richmond, to become medical director of the Rustless Iron and Steel Corporation, Baltimore, effective October 1.

Change in Health Personnel.—Dr. Peyton M. Chichester, assistant director of local health services with headquarters in Richmond, of the state health department, has been named to a similar position at Abingdon to succeed Dr. Harold M. Kelso, who has accepted a position with the Knoxville, Tenn., Health Department.

Hospital News.—Dr. John A. Shackelford, owner and operator of Shackelford Hospital, Martinsville, which was opened more than twenty years ago by his father, the late Dr. Jesse M. Shackelford, announces that the institution will be closed on the opening of the new Martinsville General Hospital. A federal grant and loan totaling \$602,000 has been made to the new project, according to *Southern Medicine and Surgery*. The 54 bed hospital is located in the downtown section of the city. When closed, all operational equipment will be moved to the new hospital and the building will be converted into business property.

WASHINGTON

State Medical Election.—Dr. George H. Anderson, Spokane, was chosen president-elect of the Washington State Medical Association at its annual meeting in Seattle, September 9-10, and Dr. Raymond L. Zech, Seattle, was inducted into the presidency. Dr. Ross D. Wright, Tacoma, was named vice president.

GENERAL

Meeting on Clinical Research.—The seventeenth annual meeting of the Central Society for Clinical Research will be held at the Drake Hotel, Chicago, November 3-4. Dr. Carl V. Moore, Washington University School of Medicine, St. Louis 10, is the secretary.

Director of Technical Education Named to Infantile Paralysis Foundation.—Miss Catherine A. Worthingham has been granted a leave of absence from Stanford University, Calif., where for the past seven years she has been director of physical therapy in the school of health (women), to become director of technical education for the National Foundation for Infantile Paralysis. Miss Worthingham will act in a liaison capacity between the National Foundation and the treatment centers throughout the United States where training courses in occupational therapy are being sponsored by the foundation.

Special Society Elections.—At the annual meeting of the Radiological Society of North America in Chicago in September Dr. Lowell S. Goin, Los Angeles, was chosen president-elect and Dr. Lewis G. Allen, Kansas City, Kan., was installed as president. Other officers are Drs. Sydney J. Hawley, Danville, Pa., Robert R. Newell, San Francisco, and John S. Bouslog, Denver, vice presidents. Dr. Donald S. Childs, Syracuse, N. Y., was reelected secretary-treasurer.—Dr. Ross Golden, New York, was named president-elect of the American Roentgen Ray Society at its recent annual meeting in Chicago and Dr. Lyell C. Kinney, San Diego, was inducted into the presidency. Other officers include Dr. Raymond C. Beeler, Indianapolis, and Comdr. Harold W. Jacox (MC) vice presidents; Dr. H. Dabney Kerr, Iowa City, secretary, and Dr. James B. Edwards, Leonia, N. J., treasurer.—Dr. Milton J. Rosenau, Chapel Hill, N. C., was chosen president-elect of the American Public Health Association at its annual meeting in New York, October 4, and Dr. John J. Sippy, Stockton, Calif., was inducted into the presidency. Vice presidents are Dr. Malcolm R. Bow, Edmonton, Canada; Carlos E. Paz-Soldan, Lima, Peru, and Marion W. Sheahan, R.N., Albany, N. Y. Dr. Reginald M. Atwater, New York, is the executive secretary and Louis I. Dublin, Ph.D., New York, was reelected treasurer.

Meeting of Urologists.—The nineteenth annual meeting of the North Central Section of the American Urological Association will be held at the Stevens Hotel, Chicago, October 19-21, under the presidency of Dr. Harry W. Plaggenmeyer, Detroit. Among the speakers will be:

- Dr. Austin I. Dodson, Richmond, Va., Renal Pathology Resulting from Nephropoiesis.
- Dr. Edward J. Stieglitz, Washington, D. C., Significance of Senescence.
- Lieut. Col. Walter M. Kearns, M.C., Postcaval Ureter; Preoperative Diagnosis; Resection and Successful Anastomosis.
- Barry J. Anson, Ph.D., Chicago, Blood Supply of the Kidneys, Suprarenal Glands and Associate Structures.
- Drs. Edward N. Cook and Francis R. Keating Jr., Rochester, Minn., Renal Stone Associated with Hyperparathyroidism.
- Drs. Robert W. McAllister and Vincent J. O'Connor, Chicago, Effect of Penicillin on Caruncle of Kidney.
- Drs. Robert H. Herbst and James W. Merriks, Chicago, Staphylococcus Allus Septicemia Following Nephrolithotomy: Recovery with Penicillin.
- Dr. Budd C. Corbus and Budd C. Corbus Jr., Evanston, Ill., Endocrine Management of Prostatic Cancer.
- Comdr. Gershon J. Thompson (MC) and Dr. Laurence F. Greene, Rochester, Transurethral Prostatic Resection in Patients with Advanced Renal Insufficiency.
- Drs. Reed M. Nesbit and Edgar A. Webb, Ann Arbor, Mich., The Use of Scrotal Skin for Covering the Denuded Penis.
- Dr. Charles C. Higgins, Cleveland, Transplantation of the Ureters into the Rectosigmoid in Infants.
- Dr. Daniel C. Moore, Chicago, The Use of Intravenous Alcohol in Surgical Patients.
- Dr. William J. McMartin, Omaha, Urological Aspects of Filariasis.
- Comdr. Robert A. Burlans (MC), Observations on Filariasis in U. S. Naval Medical Service.
- Dr. George H. Exell, Madison, Wis., An Acute Exacerbation of Brucellosis Complicating Urological Surgery.
- Major Frank C. Hamm, M.C., Renal Polyp of the Upper Calix Treated by Heminephrectomy.
- Dr. Mary Karp, Chicago, Anesthesia for the Urological Patient.

At a joint meeting with the Chicago Urological Society, Thursday evening, William C. Rose, Ph.D., Urbana, Ill., will deliver the sixteenth annual William T. Belfield Memorial Lecture on "The Amino Acid Requirements of Man."

Board of Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology will conduct its next written examination and review of case histories part I for all candidates in various cities of the United States and Canada on Saturday, Feb. 3, 1945 at 2 p. m. Candidates who successfully complete the part I examination proceed automatically to the part II examination held later in the year. All applications must be in the office of the secretary by Novem-

ber 15. All candidates are now required to be out of medical school not less than eight years, and in that time they must have completed an approved one year internship and at least three years of approved special formal training, or its equivalent, in the seven years following the intern year. The board's requirements for internships and special training are similar to those of the American Medical Association, since the board and the Association are at present cooperating in a survey of acceptable institutions. Beginning with the next written examination, which is scheduled to be held Feb. 3, 1945, the board will limit the written examination to a maximum period of three hours, and in submitting case records at this time all obstetric reports which do not include measurements either by calipers and, as indicated, by acceptable x-ray pelvimetry will be considered incomplete. All candidates are required to take the part I examination, which consists of a written examination and the submission of 25 case history abstracts, and the part II examination, which consists of an oral-clinical and pathology examination. The part I examination will be arranged so that the candidate may take it at or near his place of residence, while the part II examination will be held late in May 1945 or early June 1945 in the city nearest to the largest group of candidates.

CANADA

University News.—Group Captain George E. Hall, director of medical research for the Royal Canadian Air Force, has recently been appointed dean of the University of Western Ontario Medical School, London.—Dr. Fraser B. Gurd has been named chairman of the department of surgery at McGill University Faculty of Medicine, Montreal, succeeding Dr. Frank E. McKenty.

Special Fellowships for Chinese.—Dr. Yang Gia-liang, associate professor of surgery, West China Union University, Chengtu, has been awarded the first fellowship under a recently inaugurated program of postgraduate training for Chinese physicians at McGill University Faculty of Medicine, Montreal. The fellowships will be known as the McGill-Chinese Medical Fellowships. "In token of appreciation of the heroism of the people of China, and particularly of the magnificent work done during the past ten years of the medical profession in that country, the board of governors of McGill University has decided to award a small number of McGill-Chinese Medical Fellowships to outstanding physicians and surgeons from China." Each person awarded a fellowship will receive a senior's intern appointment at one of the teaching hospitals of the city. It was announced that because of the circumstances of the war the Chinese government will not be in a position to grant permission for many Chinese physicians to accept this offer.

LATIN AMERICA

Health Activities in Latin America.—*Institute for Hospital Administrators.*—The Inter-American Hospital Association will sponsor the second regional institute for hospital administrators in Lima, Peru, December 3-16. The director of the institute will be Dr. Guillermo Almenara, director of the Hospital Obrero, Lima, and the secretary will be Felix Lamela, Washington, D. C., executive director, Inter-American Hospital Association, Washington. The program will cover all phases of hospital operation and the faculty includes forty-eight authorities in hospital and related fields from Mexico, Central America, South America and the United States. Eleven educational institutions of Peru and eight professional and government organizations of the United States are participating in the institute, which will be held under the auspices of the Pan American Sanitary Bureau. Dr. Gustavo Baz, minister of public health and assistance of Mexico, is president of the institute and Drs. Malcolm T. MacEachern, Chicago, and Hugh S. Cumming, Washington, honorary presidents.

Society News.—The first congress on pediatrics is planned for Santiago, Chile, late in November under the auspices of the Sociedad Chilena de Pediatria.

CORRECTION

Thiourea and Thiouracil.—The word "collection" should have appeared in place of "correlation" on the sixth line from the bottom, first column, in the editorial on page 173 of *THE JOURNAL*, September 16. The word "no" should have been inserted between the words "thiouracil" and "new" on the same page, second column, fifth line from the top.

LONDON

(From Our Regular Correspondent)

Sept 9, 1944

British Empire Casualties in Five Years of War

Casualties to all ranks of the British Empire forces during the first five years of the war now amount to 925,963, which include 242,995 killed, including died of wounds, 80,603 missing, 311,500 wounded and 290,865 prisoners of war and internees. Civilian air raid casualties, casualties to merchant seamen and deaths from natural causes are excluded, together with missing personnel who subsequently rejoined, and repatriated prisoners of war.

The casualties of merchant seamen in British ships during the five years were 29,381 deaths (including deaths presumed in missing ships) and 4,192 internees. These include nationals of the dominions, India and the colonies serving in British registered ships but do not include losses in ships registered outside the United Kingdom.

Civilian air raid casualties in the United Kingdom for the five years were 56,195 killed (or missing, believed killed) and 75,897 injured and detained in hospitals.

The complete total of casualties for the fighting forces, merchant seamen and civilians is 1,091,628. These figures compare favorably with those of the four and one-quarter years of the first world war. The total casualties for the British Empire forces were 3,490,907, of which 1,089,919 were killed and 2,400,988 wounded.

The Training of the War Blinded at St. Dunstan's

The great work done by St. Dunstan's in training men blinded in the war of 1914-1918 for various occupations has been described in previous letters to THE JOURNAL, as has also the treatment of British and allied men blinded in this war. In the annual report just published, the founder, Sir Ian Fraser, M.P., reports that he has recently talked in St. Dunstan's Hospital to men who had returned from the battles in France. A few will recover useful sight, but the majority will be blind for the rest of their lives. They will shortly go to St. Dunstan's training center to "learn to be blind." Three thousand veterans of the last war and several hundred of this war have already passed through the training center. They include many Canadians and Americans as well as representatives of all our dominions and most of our allies, and men and women from most of our home defense and air raid services. The majority of the older veterans and already many of the newcomers have learned to lead normal lives and to earn their living. St. Dunstan's continues to look after blinded veterans of the last war, who are now of middle age or even old age. Nearly 1,800 still survive. St. Dunstan's in Great Britain has never been without a bed or a training place for any new patient. St. Dunstan's throughout the empire is now developing rapidly to meet the inevitable casualties which will arise from the widespread engagement of our armed forces.

Penicillin for Civilians

The use of penicillin has been almost confined to the fighting forces, as the government regarded their needs as paramount. With increased production it has been possible to allot a limited supply for civilian use. So that it may be used to the best advantage, the Ministry of Health invited the faculties of medicine and schools of universities to be responsible for its use and distribution. The ministry has issued the following list of diseases for which penicillin may be used: 1. Conditions which call for admission to a hospital if the case is otherwise suitable for treatment with penicillin: staphylococcal infection, sep-

ticemia, early acute osteomyelitis, severe carbuncle, cavernous sinus thrombosis or any other life endangering infection, hemolytic, streptococcal, pneumococcal and meningococcal infections, any life endangering infection (septicemia, pneumonia, meningitis) which has failed to respond to adequate sulfonamide treatment. Gas gangrene.

2. Conditions deserving special consideration which may be treated if supplies are sufficient: (a) injuries of the eye and infections of the conjunctiva and cornea, (b) sepsis in wounds and burns, (c) infections of the skin resistant to other treatment (syphilis, impetigo), (d) sulfonamide resisting gonorrhea, (e) acute empyema and pyogenic infections of the pleura as a complication of tuberculosis, (f) traumatic lesions, including compound fractures, extensive muscle injuries, facial injuries, injuries necessitating suture of tendon or nerve, thoracic injuries (hemothorax) and post-traumatic pneumonias.

3. Conditions not to be treated are those caused by organisms not known to be susceptible to penicillin. These include rheumatic fever, ulcerative colitis and all other intestinal infections. Bacterial endocarditis and syphilis are also excluded.

A Professor of Child Health

The council of Liverpool University has created a post which is new in this country, "professor of child health," to which it has appointed a pediatrician, Dr. Norman B. Capon, who will be part time director of a new department of child health. The establishment of the new department has been made possible by the collaboration of the university with the city council and the Royal Liverpool Children's Hospital. The cost will be shared by all three bodies. The new department will be formally opened by the minister of health in the autumn. Its establishment is a logical extension within the faculty of medicine of the university and gives practical expression to the importance of child health in the welfare of the nation. The department will be concerned not only with investigation of the diseases of children but also with the preservation of good health, physical and mental, during the early years of life. It is in such great urban centers as Liverpool that problems of child health are most pressing, while opportunities for its study and promotion are most plentiful. The new title "professor of child health" is noteworthy. Only a short time ago the title would have been "professor of children's diseases", but, as in the case of the proposed "National Health Service," we want to emphasize that health is the goal and disease a thing to be prevented.

The Representative Meeting of the British Medical Association

The annual meeting of the British Medical Association did not take place in consequence of the war. The annual representative meeting was to have been held in London in July but was postponed for the same reason. Now it is announced that the representative meeting will be held on December 5. It is of great importance this year because its main business will be to determine the policy of the association in regard to the government's proposals for a comprehensive medical service.

Marriages

DONALD G. MASON, Menominee, Mich., to Miss Catherine Ryan of North Miami, Fla., in Ann Arbor, Mich., June 16.

BONNIE CLYDE HALLEY JR., Temple, Texas, to Miss Joy Smith of Dallas in San Francisco, July 14.

THOMAS M. SPROCH, Latrobe, Pa., to Miss Joyce L. Rose of Allentown in Pittsburgh, August 19.

WILLIAM A. SAUTTER, Jackson, Mich., to Miss Marcelaine Joanne Chevre of Leslie, August 1.

ARTHUR GERARD MACK, Troy, N. Y., to Dr. JANE ANDREWS of Albany, August 19.

Deaths

Michael Hoke ☉ Beaufort, S. C.; University of Virginia Department of Medicine, Charlottesville, 1895; member of the House of Delegates of the American Medical Association in 1908; member of the Medical Association of Georgia and the American Academy of Orthopaedic Surgeons; member and past president of the American Orthopaedic Association; honorary member of the Fulton County (Ga.) Medical Society; at one time clinical professor of orthopedic surgery at the Atlanta College of Physicians and Surgeons; appointed surgeon-in-chief of the Georgia Warm Springs Foundation, Warm Springs, Ga., in 1931 and resigned in 1936; for many years on the staff of the Scottish Rite Hospital for Crippled Children, Decatur, Ga.; served as orthopedic surgeon to the Piedmont Hospital, Presbyterian Hospital, Wesley Memorial Hospital and the Tabernacle Infirmary, Atlanta; conferred the honorary degree of doctor of laws by the University of North Carolina in 1931; died September 24, aged 70.

William Jerome Arlitz ☉ Hoboken, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1890; Baltimore Medical College, 1897; fellow of the American College of Surgeons; for many years police surgeon; served during World War I; member of the staffs of the Christ Hospital, Jersey City, New Jersey State Hospital, Greystone Park, North Hudson Hospital, Weehawken, and the Moses Taylor Hospital, Scranton, Pa.; formerly on the staff of St. Mary's Hospital; served as chief surgeon of the Lackawanna Railroad and Public Service Corporation of New Jersey and the New York Central and Lehigh Valley railroads; died in Elizabethtown, N. Y., August 22, aged 75.

Grover Cleveland Weil ☉ Pittsburgh; University of Pittsburgh School of Medicine, 1910; associate professor of surgery at his alma mater; specialist certified by the American Board of Surgery; member of the American Society of Clinical Pathologists, American Association for the Surgery of Trauma, American Association of Railway Surgeons and the American Association of Pathologists and Bacteriologists; fellow of the American College of Surgeons; on the staff of the Mersey Hospital; chief surgeon for the Pittsburgh Coal Company; died in Lake Placid, N. Y., August 17, aged 59, of coronary heart disease.

Enoch Marvin Mason ☉ Birmingham, Ala.; Johns Hopkins University School of Medicine, Baltimore, 1906; past president of the Jefferson County Medical Society; member of the Southern Medical Association; served as councilor of the Ninth District of the Medical Association of the State of Alabama; specialist certified by the American Board of Internal Medicine; veteran of the Spanish-American War and World War I; at one time director of laboratories of the state board of health at Montgomery; visiting physician on the staff of St. Vincent's Hospital; medical director of the Alabama Power Company; died August 14, aged 66.

Hugh Loyd Davison ☉ Champaign, Ill.; University of Pennsylvania School of Medicine, Philadelphia, 1924; fellow of the American College of Surgeons; member of the John B. Deaver Surgical Society; formerly physician for the Pennsylvania Railroad Company; at one time fellow in surgery at the Mayo Foundation in Rochester, Minn.; served during World War I; on the staffs of the Champaign County and Carle Memorial hospitals in Urbana, serving as chief of staff and director of the latter; a founder of the Carle Hospital Clinic; died in Benton Harbor, Mich., August 24, aged 47, of coronary occlusion.

David A. Holland, Mahanoy City, Pa.; Medico-Chirurgical College of Philadelphia, 1903; member of the Medical Society of the State of Pennsylvania; formerly served as a member and president of the city school board; school director for twenty years; a member of the board of directors of the Schuylkill County Crippled Children's Society and of the Union National Bank; surgeon for the Reading Coal and Iron Company and for the Reading and Lehigh Valley railroads; on the staff of the Locust Mountain State Hospital, Shenandoah; died July 16, aged 63, of chronic osteomyelitis of the right leg.

John Elmer Virden ☉ New York; Bellevue Hospital Medical College, New York, 1890; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Ophthalmology; formerly associate professor of clinical ophthalmology at the New York Post-Graduate Medical School and Hospital, Columbia University; visiting ophthalmologist,

Union Hospital; consulting ophthalmologist, Westchester Square and Lincoln hospitals, Bronx Eye and Ear Infirmary, and Home for Incurables; died August 30, aged 81.

Samuel Treat Armstrong ☉ Katonah, N. Y.; St. Louis Medical College, 1879; member of the American Psychiatric Association, Association for Research in Nervous and Mental Diseases, American Association for the Advancement of Science and the New York Academy of Sciences; from 1881 to 1890 had been with the U. S. Marine Hospital Service; veteran of the Spanish-American War; received the Companion Military Order of Foreign Wars and the Order of the Spanish-American War; medical director of the Hillbourne Farms, where he died August 31, aged 84, of cerebral thrombosis.

Spencer Lyman Dawes, Kingston, N. Y.; Bellevue Hospital Medical College, New York, 1887; formerly adjunct professor of materia medica at the Albany Medical College; medical examiner in the state department of mental hygiene from 1919 to 1935; secretary and executive officer of the Commission on Federal Legislation for Alien Insane when it was created by the state legislature in 1914; served as medical examiner for the State Bureau of Deportation; formerly consulting physician of Kingston City Hospital; died in the Orthmann Sanitarium, July 13, aged 80, of cerebral hemorrhage.

Frederick Henry Dillingham ☉ New York; College of Physicians and Surgeons, New York, 1880; professor of dermatology and syphilology at the New York Polyclinic Medical School and Hospital; fellow of the New York Academy of Medicine; for many years assistant sanitary inspector for the New York City Board of Health; consulting dermatologist to St. Francis and St. John's Riverside hospitals and dermatologist to St. Joseph's Hospital in Yonkers; died in the New York Polyclinic Hospital August 30, aged 87, of bronchopneumonia.

Edward Holden Blair ☉ Wethersfield, Conn.; College of Physicians and Surgeons, Baltimore, 1906; member of the American Academy of Pediatrics and the New England Pediatric Society; served in the medical corps of the U. S. Army during World War I; consultant on the staff of Hartford Hospital; school physician; died in Hartford August 14, aged 65, of coronary thrombosis.

Carrie Simpson Coleman Burr, Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; died in the University Hospital July 1, aged 76, of gastric carcinoma.

Martha Nancy Canfield, Redlands, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1908; formerly on the staff of the Battle Creek Sanitarium, Battle Creek, Mich.; served as resident physician at the Loma Linda Sanitarium and Hospital, Loma Linda; died July 28, aged 77, of hypertensive cardiovascular disease.

Wellman Franklin Chaffin, Raymore, Mo.; State University of Iowa College of Medicine, Iowa City, 1890; member of the Missouri State Medical Association; served during World War I; past president and secretary of the Cass County Medical Society; died July 30, aged 77, of cerebral hemorrhage.

George A. Clement, Spencer, N. C.; Leonard Medical School, Raleigh, 1905; died June 29, aged 73, of cerebral hemorrhage.

Mark A. Conway, Locust Gap, Pa.; Temple University School of Medicine, Philadelphia, 1917; member of the Medical Society of the State of Pennsylvania; died July 31, aged 49, of coronary thrombosis.

J. Demorest Curtis, Detroit; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; member of the auxiliary staff, Providence Hospital; died at Houghton Lake, Mich., August 29, aged 59, of coronary heart disease.

Joseph Elbert Daniel ☉ Houston, Texas; Memphis (Tenn.) Hospital Medical College, 1901; for many years medical director of the Great Southern Life Insurance Company; died July 22, aged 66, of cerebral hemorrhage.

William R. S. Denner, Manchester, Md.; Johns Hopkins University School of Medicine, Baltimore, 1908; resident physician at the Western Pennsylvania Hospital, Pittsburgh, 1908-1909; resident pathologist at St. Francis Hospital, Pittsburgh, from 1909 to 1912; at one time served as associate in pathology at the University of Pittsburgh School of Medicine; member of the extraurban staff, Union Memorial Hospital, Baltimore; vice president of the Farmers and Mechanics Bank of Westminster; died July 3, aged 61, of carcinoma of the prostate.

William Henry Egan, New York; Bellevue Hospital Medical College, New York, 1895; served as president of the

reducing a fractured limb depends entirely upon the circumstances of the particular case. The question as to whether the reduction and treatment of a fractured limb without the use of an x-ray machine constitutes negligence depends upon what an ordinarily skilled physician practicing in that vicinity, in the exercise of due care and professional judgment, would be required to do under like circumstances. The determination of those questions depends upon expert testimony. (*Perkins v. Trueblood*, 180 Cal. 437, 443, 181 P. 642; *Arais v. Kalensnikoff* [10 Cal. 2d 428], 74 P. 2d 1043 [115 A. L. R. 163].)

The evidence in this case, continued the court, shows that the physician did know the nature of his patient's injury and there is no evidence that his treatment would or should have been any different if roentgenograms had been taken. Nor is there any showing that his treatment in any way caused the deformation of the finger. The only medical testimony in the case was given by the physician himself to the effect that the present condition of the finger was caused by arthritis. Even assuming that the physician might have discovered the arthritis sooner if he had taken roentgenograms sooner, the failure to do so would constitute a mere error of judgment, not actionable negligence, as was said in *Bickford v. Lawson*, supra:

From a careful reading of the entire record we are convinced that the only omission of which the plaintiff may reasonably complain is a failure to use x-ray pictures after the reducing of the fracture, at an earlier date, with the possibility that the defendant might have thus discovered the lack of callus and that he would then have advised his patient to consult a bone specialist. But the defendant testified that he had no intimation of that lack of callus until the x-ray picture was taken December 20 [two months after the injury]. That omission, if it may be said to have contributed to the injury of the patient, was a mere error in judgment which does not constitute actionable malpractice.

The patient contended that the testimony of the physician himself was sufficient to establish negligence on his part; that there is a material variance between the treatment outlined by him as being in accord with good practice and that actually administered by him as described by the patient. However, said the court, the record does not show any substantial conflict of testimony in this regard. The defendant described in detail his method of applying splints to the injured finger, stating that "the finger was splinted in as full extension as possible, that is, with the finger sticking out straight"; "with two of these splints applied and tape wrapped around them tightly, the finger must be extended straight out, or as near so as it was humanly possible to get it." He further testified, with reference to his first use of a splint, that "at the time this finger was splinted it was still slightly swollen and inflamed from the crushing force of her injury. The finger was brought up in as full extension as possible, and that is all that anybody can do to reduce that type of fracture." (Italics added.) These statements are not inconsistent with plaintiff's assertion that "the finger was not straightened out when the splint was put on"; that "he did put splints on it and left it crooked the way it was at that time, with the splints on, he didn't straighten it out with the splints on." She herself testified that on that occasion "the finger was so swollen still and so crooked that he could not manipulate the finger even yet," from which statement it is manifest that the attainment of full extension was not then possible.

Finally, the patient contended that a jury should have passed on the evidence because of the testimony of herself and of her husband that in the course of a conversation between them and the physician sometime subsequent to the termination of the physician's services he admitted that she had asked him over and over again for "x-ray" and that "I know it is not your fault . . . It is all my own." The general rule, stated the court, is, however, that an admission to be sufficient must be an admission of negligence or lack of the skill ordinarily required for the performance of the work undertaken. *Markart v. Zeimer*, 67 Cal. App. 363, 227 P. 683. Where the admission does not amount to an admission of negligence, it is held that the physician is not responsible. *Phillips v. Powell*, 210 Cal. 39, 290 P. 441, 443. In that case a blade used in making an incision broke and became embedded in the flesh, and testimony was introduced that the defendant had said "It is my fault in using that kind of blade in that kind of an operation." The court there said "We are of the opinion that these statements or otherwise did not constitute admissions that the defendants 'did not possess and use that reasonable degree of learning and skill which was ordinarily possessed by the members of their profession in good standing practicing in their vicinity,' which

is the only standard by which the liability of the defendants may be determined. See *Markart v. Zeimer*, 67 Cal. App. 363, 371, 227 P. 683; *Hesler v. California Hospital Co.*, 178 Cal. 764, 174 P. 654; *Perkins v. Trueblood*, 180 Cal. 437, 181 P. 642." And even where a physician admits that he was in error in the treatment administered (*Donahoo v. Lovos*, 105 Cal. App. 705, 288 P. 698) or that he performed the wrong operation (*Markart v. Zeimer*, supra), it is held that such admissions are not sufficient to establish liability, where the admissions are not of negligence. As said in the latter case [67 Cal. App. 363, 227 P. 686]:

These admissions, therefore, are not admissions that the operation complained of was not performed with reasonable care, or that the defendants did not possess and use that reasonable degree of learning and skill which was ordinarily possessed by the members of their profession in good standing practicing in their vicinity. As a consequence, while they were competent as evidence of such facts as they admitted, they did not supply the absence of expert testimony in such particulars as expert testimony was otherwise required.

Here the alleged admission pertained only to the failure of the defendant to obtain x-rays of the broken finger; and, at most, the uncontradicted evidence shows that x-rays would merely have enabled him to obtain more positive evidence of the nature of the injury sustained, in confirmation of facts with which he was already familiar by observation and palpation. They would not have affected his method of treatment in the least; nor is there any evidence to show that the result would have been any different.

The plaintiff in support of the contention just discussed cited *Scott v. Sciaroni*, 66 Cal. App. 577, 226 P. 827, and *Walter v. England*, 133 Cal. App. 676, 24 P. 2d 930. In both of these cases, the court said, the admissions were of negligence, not of mere mistake, and therefore those cases are not controlling here. In *Scott v. Sciaroni*, supra, the defendant was reported to have said that he left the radium on too long, that it was his fault that the plaintiff was in her present condition. In distinguishing that case, it was said in *Donahoo v. Lovos*, 105 Cal. App. 705, 288 P. 701: "In that case the physician admitted that the condition of the plaintiff was due to his negligence." In *Walter v. England*, 133 Cal. App. 676, 24 P. 2d 934, the defendant stated that he had made a mistake in inserting a hypodermic needle, and it was held: "We are satisfied that, as used by the defendant, the word 'mistake' was synonymous with the word 'negligence.'"

The appellate court accordingly affirmed the judgment of nonsuit entered by the trial court.—*Lashley v. Koerber*, 150 P. (2d) 272 (Calif., 1944).

Society Proceedings

COMING MEETINGS

- American Academy of Pediatrics, St. Louis, Nov. 9-11. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.
- Annual Conference of State Secretaries and Editors, Chicago, Nov. 17-18. Dr. Olin West, 535 N. Dearborn St., Chicago, Secretary.
- Association of American Medical Colleges, Detroit, Oct. 23-25. Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.
- Association of Military Surgeons of the United States, New York, Nov. 2-4. Col. James M. Phalen, Army Medical Museum, Washington 25, D. C., Secretary.
- Central Neuropsychiatric Association, Chicago, October 31. Dr. Ernest M. Hammes, 1124 Lowry Medical Arts Bldg., St. Paul 2, Minn., President.
- Inter-State Postgraduate Medical Association of North America, Chicago, Oct. 17-20. Dr. Arthur G. Sullivan, 16 N. Carroll St., Madison, Wis., Managing Director.
- Midwestern Section of American Federation for Clinical Research, Chicago, Nov. 2. Dr. Richard H. Lyons, University Hospital, Ann Arbor, Mich., Secretary.
- Oklahoma City Clinical Society, Oklahoma City, Oct. 23-26. Dr. L. C. McHenry, 512 Medical Arts Bldg., Oklahoma City, Secretary.
- Omaha Mid-West Clinical Society, Omaha, Nebraska, Oct. 23-27. Dr. J. D. McCarthy, 1036 Medical Arts Bldg., Omaha 2, Secretary.
- Southern Medical Association, St. Louis, Mo., Nov. 13-16. Mr. C. P. Loranz, Empire Building, Birmingham 3, Ala., Secretary.
- Virginia Medical Society of, Richmond, Oct. 23-25. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.
- Western Surgical Association, Chicago, Dec. 1-2. Dr. Arthur R. Metz, 250 East Superior St., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- *Continuous Recording Electrocardiography. W. B. Likoff, M. B. Rappaport and S. A. Levine—p. 98.

Heart in Rheumatoid Arthritis.—Young and Schwedel point out that in Europe a common etiologic background for chronic rheumatoid arthritis and rheumatic heart disease has been widely accepted. The prevailing opinion in this country has been that, when chronic structural joint changes and evidence of rheumatic carditis coexist, it is a rare combination of two distinct clinical entities. This concept of an etiologic difference persists because of a lack of postmortem studies on a sufficiently large number of patients with rheumatoid arthritis. The authors report postmortem and clinical data on 38 adults with rheumatoid arthritis. Thirty-three of the patients had cardiac lesions which were not the result of hypertension or coronary artery disease. In 25 of the 33 the process was rheumatic in origin and in the remaining 8 of a nonspecific infectious nature. An active rheumatic process was present in only 6. A history of rheumatic fever was obtained in only 3 cases and of probable rheumatic fever in 2 others. The arthritis was insidious and progressive in 18 cases, and acute attacks of polyarthritis occurred in 15 during the course of the disease. The extremely high incidence of rheumatic heart disease in rheumatoid arthritis which was found in this and previous pathologic studies suggests an extremely close relationship which should lead to consideration of the possibility that they may be manifestations of the same underlying disease process.

Coarctation of Aorta.—Perlman found the incidence of coarctation of the aorta in adults to be 1 in 10,000, as contrasted with 1 in 1,500 in reports of other investigators. He reports 13 cases detected in the course of routine physical examinations for army service of an unselected group of men between the ages of 18 and 35 years. In only 3 of the 13 cases were pulsations of the femoral artery present. In only 1 of the 3 was the femoral impulse of moderate intensity, and even in this instance the impulse did not approach the intensity of the radial artery pulsation. In the remaining 2 cases the femoral artery pulsation might be classed as slight. The basal diastolic was the predominant cardiac murmur. Although the diagnosis of coarctation of the aorta may be made clinically, the roentgenogram is a valuable diagnostic aid. In some cases confirmatory evidence from the roentgenogram is essential for the diagnosis. The characteristic radiologic syndrome consists of (1) absence of the aortic knob, (2) dilatation of the ascending and transverse portions of the arch of the aorta, (3) erosion of the lower margin of the posterior portions of the ribs and (4) roundness or enlargement of the left ventricle. The only constant radiologic signs in this series were absence of the aortic knob and erosion of the ribs.

Myocardial Infarction Indicated by Angina Pectoris.—Dressler reports 16 cases in which there was clinical and laboratory evidence suggestive of myocardial infarction in the absence of characteristic, severe and protracted anginal attacks. In 9 cases myocardial infarction was indicated by the sudden onset or aggravation of angina of effort; in 7 it was clinically signalized by brief attacks of angina of rest, lasting up to twenty minutes. The seriousness of such atypical anginal manifestations is often unrecognized, and proper management of the patient is neglected. Sudden death is frequent in this group. A painstaking history, including an accurate estimate of the functional capacity of the heart and a comparison of present and past performances, furnishes the most significant diagnostic data. An increase in the sedimentation rate is often a more sensitive index of myocardial necrosis than the electrocardiographic changes. Lack of the latter should never be considered as conclusive evidence against serious myocardial involvement. Anginal pain of the type described has often been designated as "premonitory pain" which precedes the development of "actual myocardial infarction." The author's experience, as well as reports in the literature, proves that "premonitory pain" is not invariably followed by typical anginal attacks signifying myocardial infarction. "Premonitory pain" is often by itself associated with evidence of myocardial necrosis. The distinction between "premonitory pain" and "actual myocardial infarction" is inappropriate. A sudden onset or aggravation of angina of effort, or brief attacks of angina of rest, indicates progressive coronary insufficiency and is in the majority of cases associated with ischemic myocardial necrosis.

Continuous Recording Electrocardiography.—Likoff and his collaborators present a description of a continuous recording electrocardiograph. The apparatus is capable of taking a miniature record one-twentieth normal size on ordinary moving picture film and of functioning for 267 hours without the attention of an operator. A simple enlarger was devised to view the miniature record at normal size and to make suitable photographic reproductions. The apparatus is as accurate and sturdy as the ordinary portable electrocardiograph. Several interesting observations have been noted thus far. Ventricular fibrillation has been found to follow, rather than precede, death in some cases. Electrocardiographic curve generally regarded as indicative of ventricular fibrillation have been observed to occur while heart beats were audible and therefore are better designated as ventricular flutter.

Buffy Layer in Rapid Diagnosis of Septicemia.—Sincars from the "buffy layer" or "leukocytic cream" have been employed to facilitate leukocytic differential counts in leukopenic conditions. Malarial parasites are more numerous in the red cells in this layer, owing to their decreased mass. Humphrey describes demonstration of the causative organism of septicemia in this layer in the following manner. At the time of withdrawing blood for culture, 4 to 7 cc. of blood is placed in a narrow tube which contains some dry oxalate crystals. After mixing the blood and the oxalate by shaking, the tube is centrifuged at high speed for thirty minutes. The plasma is gently removed from the packed erythrocytes and overlying buffy layer with a capillary pipet, care being taken not to disturb the latter. The layer is then gently scraped off the underlying red cell strata with a small loop or is sucked up with a

capillary pipet and smeared over slides, which are stained with Gram's stain in the usual manner. It is advisable to stain one slide with Wright's blood stain, as it was found that gram negative diplococci were more readily found in such preparations and their gram staining characteristics could later be checked. While in some cases several intracellular and extracellular bacteria were observed in one field, others required close examination for almost an hour before definite bacterial forms could be seen. The author describes 6 cases in which this method was employed. The advantage of this procedure is that rational therapy can be instituted within an hour after the clinical diagnosis of septicemia is made, making it unnecessary to wait forty-eight or seventy-two hours until a blood culture becomes positive. The procedure is intended to supplement the blood culture.

Chemistry of Ovarian Cysts.—Watts and Adair determined the sodium, potassium, chloride, nitrogen, nonprotein nitrogen, protein, glucose, total solid, water, ash and specific gravity of 29 ovarian cyst fluids from 15 ovarian tumors (9 benign and 6 malignant); fluids from 3 parovarian cysts have been examined. Values vary greatly not only among the fluids of different types of cysts but also between the fluids of the different cavities of the same tumor. The composition of the fluid seems to vary with the secretory activity of the lining of the cyst. In general, fluids from cysts with actively secreting epithelium and a cellular basal layer are high in nitrogen and protein, high in potassium and low in chloride; those with less actively secreting epithelium, or a cyst wall which is denuded or attenuated and in which the basal layer is avascular or hyalinized, show low nitrogen and protein, low potassium and high chloride.

Cord Transfusions in Newborn Infants.—Mayes made 34 cord transfusions in newborn infants; 18 in infants weighing less than 5½ pounds, gestation from 23 to 39 weeks; 16 in infants weighing 5½ pounds and over, 13 full term, 3 with gestation of 36 weeks or under. There were 4 deaths, 3 in the smaller weight group, 1 in the larger. The citrated blood to be given should be in readiness before the baby is delivered. A 50 cc. syringe is used in which is 5 cc. of a 2 per cent solution of sodium citrate. The blood is withdrawn and the syringe tilted several times to mix the citrate solution with it. If the mother is toxic or if for any other reason her blood is not desirable, blood from the father, from some other donor or from the bank may be used. As soon as the baby is born and before cutting the cord, the umbilical vein may be entered with the same needle used to withdraw the blood. If preferred a cannula may be placed in the vein. The transfusion should be started as far from the baby as possible. This serves two purposes: If the vein is not easily entered, another attempt can be made nearer the baby; if the baby should move, the needle will not be disturbed. As soon as the transfusion is started the cord should be clamped between the needle and the placenta.

If it is decided to cut the cord before giving the transfusion, the cord may be gently compressed near the umbilicus, so that the veins remain distended. The transfusion should be given slowly, 30 or 40 cc. in about five minutes. About 10 cc. per pound of baby is sufficient. Premature infants and particularly those usually considered nonviable are benefited. In infants suffering from difficult delivery and those in doubtful condition, a small transfusion of 20 cc. of mother's blood acts as a direct stimulation to the respiratory center and tends to overcome a tendency toward hemorrhage. If the mother gives a history of previous stillbirths or if hemorrhagic disease or erythroblastosis is suspected, cord transfusions may be of benefit.

Frequency of Anovulatory Menstruation as Determined by Endometrial Biopsy.—Levan and Szanto took endometrial biopsies from 103 women at the Kankakee State Hospital. All had regular menstrual periods. Biopsies were taken twenty days or more following the last menstrual period. The specimens were stained with hematoxylin and eosin. In doubtful cases Best's carmine stain for glycogen and the thionin stain for mucin were used. The authors obtained 261 endometrial biopsies during the last third of the menstrual cycle from 103 women. Fourteen anovulatory cycles were found in 9 patients. Two patients showed successive anovulatory cycles; 7 patients showed both anovulatory and ovulatory cycles. The incidence of anovulatory cycles was 5.36 per cent; the patients with anovulatory cycles amounted to 8.7 per cent of the total number examined. Parity was not found to be a factor, but women past 40 years of age showed a higher incidence of anovulatory menstruation. While all the women in this group are psychotic, the incidence of anovulatory menstruation in them compares quite closely with that found in normal, healthy women.

Plasma Fixation of Skin Grafts.—Sheehan directs attention to the change in the technique of skin grafts introduced by Sano of Temple University (abstract in *THE JOURNAL*, Dec. 25, 1943, p. 1143). Painting the host site with the patient's own plasma and the graft with leukocyte cell extract makes the adhesion perfect, sutures are unnecessary, the degree of pressure is no longer a problem and the circulation within the graft is established so rapidly that overlapping edges bleed when cut on the second day. On the fourteenth day definite recovery is achieved and in two months the graft is indistinguishable in coloration or by its boundaries from the neighboring skin. It is not good practice to have the skin edges overlap the defect. In cutting it away an unsatisfactory apposition at the defect skin edges is inevitable. Stretching by roller pressure, on the contrary, banks the graft edges accurately against those of the defect, a little cardboard and hand pressure is added and the approximation is maintained sufficiently by means of a few clamps. Adhesion is immediate and complete. The compound was able to seal wounded liver tissues in which suturing leads only to bleeding and to be of equal effect when employed on wounds of the spleen. It is invaluable in facial injuries in which there are flaps of torn skin whose immediate return is

of high importance and in the elimination of disfiguring scar. It should make possible the closure of many not too large wounds without sutures. It offers great hope of application in many situations, as in the face and hands.

Peptic Ulcer Perforating into Abdominal Wall.—Morlock and Walters observed a jejunal ulcer which had perforated into the anterior abdominal wall. Two similar cases were found in the files of the Mayo Clinic. All of the 3 patients had had a previous anterior gastrojejunostomy. In each instance the offending lesion was an ulcer arising in the anterior rim of the anterior gastrojejunal stoma. In order that a peptic ulcer may attach itself to the anterior abdominal wall and penetrate into it the ulcer must have its origin from a part of the stomach wall which is adjacent to the abdominal wall. A gastrojejunal ulcer arising on the anterior rim of an anterior gastrojejunal stoma is therefore peculiarly likely to penetrate in such a way as to result in this complication. In the surgical treatment of duodenal ulcer, posterior anastomosis is always done in preference to the anterior anastomosis. A better functional result is achieved by the former procedure. Anterior gastrojejunostomy is done only when posterior anastomosis is not technically feasible, and this is uncommon. For these reasons few gastrojejunal ulcers are situated in a location which makes penetration of the ulcer into the anterior abdominal wall anatomically possible. Although it is possible for a gastric ulcer having its origin in a part of the anterior gastric wall adjacent to the anterior abdominal wall to penetrate into the abdominal wall, this complication must be exceedingly rare in a stomach which has not been previously disturbed by operation. In 1 case 2 ulcers were found to penetrate into the anterior abdominal wall; 1 had its origin in the gastric wall; the other arose from the jejunum. Peptic ulcer which perforates into the anterior abdominal wall must be treated surgically.

Pathogenesis of Intermittent Exophthalmos.—According to Walsh and Dandy intermittent exophthalmos is characterized by rapid protrusion of one eye when venous stasis is induced by bending the head forward, by lowering the head, by turning the head forcibly, by hyperextension of the neck, by coughing, by forced expiration with or without compression of the nostrils and by pressure on the jugular veins. The ocular protrusion disappears immediately when the head is erect and when arti-

ficially induced venous congestion is relieved. Usually there is enophthalmos when venous congestion does not exist. Pulsation of the eyeball may or may not be present, and vision may or may not be affected. The condition is progressive and may be productive of unbearable pain and troublesome diplopia. The authors report a case in which the quick protrusion and sinking of the eyeball with the postural changes, and the rapid protrusion induced by coughing, sneezing and jugular compression could mean only the filling of a large venous bed. The pulsation of the eyeball indicated an arterial component. The lesion was considered to be an arteriovenous aneurysm. The enophthalmos (with the patient, a girl aged 18, sitting or standing) was thought to be due to atrophy of the orbital fat from long continued pressure. A transcranial approach disclosed an intracranial arteriovenous aneurysm lying in and behind the sphenoid fissure. The case is the only one in the literature in which a cause for this rare syndrome has been disclosed. An arteriovenous aneurysm of similar type is probably responsible in all cases for pulsation of the eyeball. In most recorded cases pulsation was absent or muffled. Whether or not there are two types of this syndrome, one with and the other without pulsation, cannot be determined without subsequent pathologic studies. The intermittent exophthalmos was cured by obliterating the aneurysm with the electrocautery, but blindness of the affected eye and ophthalmoplegia resulted.

Keratectomies for Treatment of Corneal Opacities.—Castroviejo states that among the corneal opacities covering the pupillary area there are some susceptible of treatment by corneal transplantation, which gives the best results as far as improvement of vision is concerned. There are other superficial opacities in the pupillary area which, although lending themselves to treatment by corneal transplantation, are best handled by other surgical procedures which expose the eye to fewer complications. For some of these conditions superficial keratectomy is the preferred procedure. Keratectomy may be partial, when only a limited area of the external lamella of the cornea is excised, or total, when the excision extends over the whole area of the cornea. The author performs a partial superficial keratectomy for band keratitis, for dystrophica adiposa corneae and for leukoma. He employs total superficial keratectomy for vascularized leukoma. Total superficial keratectomy together with corneococonjunctival plastic surgery is carried out in vascularized leukoma and symblepharon. Occasionally in cases of severe symblepharon the author combines partial superficial keratectomy, corneococonjunctivoplasty and graft of the buccal mucous membrane. He employs partial superficial keratectomy and graft of the buccal mucous membrane for the treatment of recurrent pterygium. In selected cases superficial keratectomy offers the ideal method of improving visual acuity. Penicillin ointment has been found to shorten the period of healing and reduce the occurrence of infection.

*Id. Hartford Circus Fire Patients in Hospitals S. B. Weld—p. 511.

Hartford Circus Fire Patients in Hospitals.—Because of its proximity to the scene of the disaster, the Municipal Hospital received the first and, in the end, the largest number of patients. During the following eight minutes 143 patients were admitted. Of this number 5 were dead on arrival, 6 others were so severely burned that they died within an hour after admission, 42 were treated in the outpatient department and 76 were receiving treatment up till 8 p. m., when 22 of the least seriously burned were transferred in U. S. Army ambulances to

Hartford and St. Francis hospitals. The procedure at the Municipal Hospital was similar to that followed in the other hospitals. All patients were given morphine subcutaneously on admission. Plasma was administered intravenously under considerable difficulty, owing to the badly burned condition of the skin on the extremities and to destruction or collapse of superficial veins. It was often necessary to cut down on the femoral veins. The dressing teams applied petrolatum impregnated gauze to all burned areas without débridement. These dressings were covered with light plaster casts for even pressure and changed the following day to Ace bandages. A tetanus detail tested patients for reactors and gave prophylactic injections. Sulfonamides were administered during the first twenty-four hours together with forced fluids by mouth, if tolerated. Parenteral fluids were necessary in many instances because of nausea. Patients developing fever on the second day were given penicillin in liberal doses. This major disaster found Hartford ready to meet the task imposed. When the facts are tabulated and analyzed there will be on record not only data of inestimable value to medical science but evidence of the necessity for a permanent comprehensive emergency organization.

Liver and Gallbladder in Excretion of Sulfonamides.—Shay and his associates investigated sulfanilylguanidine, succinylsulfathiazole, phthalylsulfathiazole and sulfathiazole. Experiments carried out on 30 dogs demonstrated that sulfathiazole is concentrated by the dog's liver in a constant relationship to the blood level, the ratio being independent of the blood concentration. The introduction of the succinyl radical into the sulfathiazole molecule at N¹ resulted in a considerable increase in the hepatic bile/blood concentration ratio, while the introduction of the phthalyl radical in the same position increased the ratio many times more, so that the removal from the blood of the latter compound by the liver reaches a high degree of selectivity. Sulfaguanidine appears to be excreted by the liver at approximately the blood level. Phthalylsulfathiazole appears to be partially broken down in the dog's liver with the liberation of a free sulfonamide, presumably sulfathiazole. The normal dog's gallbladder concentrates sulfathiazole, succinylsulfathiazole and phthalylsulfathiazole in proportion to water absorbed from the bile. It neither excretes nor absorbs any of these drugs but is able to absorb sulfaguanidine.

Histopathology of Progressive Muscular Dystrophy Revealed by Ultraviolet Photomicrography.—According to Hoagland and his associates morphologic studies of diseased muscle have yielded little information concerning the fundamental defect responsible for the extensive atrophy and dystrophy in the primary muscle disorders. The recent development of a simplified quartz microscope with the 2,537 angstrom line of mercury as the light source has made it possible to obtain ultraviolet photomicrographs of tissues fixed, embedded and sectioned by routine methods. Differences in the absorptive capacity of the organic components of tissue may be expected to result when photographed with the 2,537 angstrom line of mercury. The proteins have a maximum absorption at 2,800 angstroms and the nucleoproteins in the region 2,600 to 2,700 angstroms. Nucleic acid has a maximum absorption at 2,600 angstroms with an extinction coefficient from thirty to sixty times that of the proteins. Changes in tissue structure which result from differences in distribution or concentration should be readily detected by this method. Results, therefore, which are quite different from those obtained with conventional staining technic may be expected, since the ultraviolet photomicrographs are a reflection principally of the chemical nature of the material, while photomicrographs of stained sections reflect merely the absorptive capacity of the dyes used in staining. The authors report a histopathologic study of material obtained from fifteen biopsies of muscle of patients with progressive muscular dystrophy. An exact description of the microscopic changes occurring in this syndrome as revealed by photomicrographs in ultraviolet light is difficult at this time because of lack of an adequate system of nomenclature. Attention has been drawn to lesions of consistent character found in sections of muscle removed at biopsy which appear to be specific for the disease.

Cadmium Chloride-Aerosol Solution in Treatment of Epidermophytosis and Bromidrosis.—Watts administered cadmium chloride-aerosol solution to 70 patients with intertriginous epidermophytosis. The treatment was continued daily for from two to four weeks; the itching was controlled and the drying effect of the solution was observed after a few days.

All patients were cured under this regimen. The 14 patients with hyperkeratotic type of epidermophytosis were required to soak their feet in the cadmium chloride-aerosol solution ten minutes daily, after which the feet were massaged vigorously, thereby removing much of the infected epidermis. To date none of these patients have been cured, but they show improvement. The solution was nonirritating. Two cases of epidermophytosis of the hands and 1 case of tinea circinata were successfully treated. Sixteen female patients who suffered severely from bromidrosis, manifested as odorous underarm perspiration, were treated by bathing and applying the solution under the arm with the finger tips. The results have been highly satisfactory in all. Treatment with cadmium chloride-aerosol solution completely controlled the objectionable odor in 6 cases of bromidrosis of the feet.

Repair of Cranial Defects with Tantalum.—According to Robertson, tantalum is a heavy metal with a density about twice that of steel. Its chemical inertia obviates reactions to body fluids. Tantalum is workable when cold but cannot be cast. Strength and thermal conductivity are approximately those of steel. Tantalum sheet metal from 0.015 to 0.02 inch thick has been used to repair skull defects at Brooke General Hospital, Fort Sam Houston, Texas. Two methods of cranioplasty with tantalum have been used: a two stage operation and a one stage procedure. In the former the bed for the plate is prepared by mortising the periphery of the bone defect. A shelf is made in the outer table by chisel or burr 2 to 3 mm. beyond the limit of the defect. An impression of the defect and details of the margin of bone is obtained. A wax model is made duplicating the contour of the portion of the skull to be replaced. From this positive a die and counter die are made to swage the metal to conform to size, shape and contour of the missing bone. At a secondary operation the plate is placed in the previously prepared bed and fixed in position. The more frequently employed and highly satisfactory method is a one stage procedure. The bed is prepared as described. The approximate size segment of tantalum is molded by bending and shaping or more frequently by "beating" to contour. Then the exact outline is cut with heavy scissors to conform to the outline of the mortised defect. One border of the plate is engaged into the shoulder of the mortise and, by slight bending and forcing the opposite border into its corresponding shoulder the plate will fit so well when it has flattened out as a result of its inherent spring that it will lock itself into position. Fixation of the tantalum replacement may be accomplished by wire suture or by using small triangular trimmings of the tantalum sheet, utilizing the principle of glazier's points. Tantalum cranioplasty has been done on 26 service men. The author stresses the ease with which the cranial repair has been made, the efficiency of the repair and the cosmetic results. Four illustrative cases are reported in detail. The chief advantages of tantalum from a surgical point of view are its chemical and electrical inertia and ductility.

Differential Diagnosis of Intraspinal Tumors and Protruded Intervertebral Disks.—Love argues that if diagnostic errors are to be kept at a minimum the mistake should not be made of considering every intractable low back and sciatic pain as being due to a protruded intervertebral disk. Trauma

may initiate symptoms of intraspinal neoplasm as well as those of a protruded intravertebral disk. It is important in planning and executing the operation for relief of intraspinal pressure to know which of the following is indicated: relatively extensive laminectomy for removal of a tumor or a relatively short operation, with little or no sacrifice of bone, for removal of a protruded intervertebral disk. The author and his colleagues at the Mayo clinic encountered many intraspinal neoplasms masquerading as protruded intervertebral disks. In some cases the mimicry was so close that the differential diagnosis could not be made until the space taking lesion had been uncovered at the operating table, in spite of the fact that every patient suspected of having a protruded intervertebral disk is subjected in addition to a general physical, orthopedic and neurologic examination. In an analysis of the records of 26 cases of tumor of the spinal canal in which symptoms of root pain suggested irritation or compression of the spinal cord or nerve roots by a protruded intervertebral disk it was found that diagnostic spinal puncture, with or without visualization of the spinal canal, was essential to diagnosis and to localization of the intraspinal lesion. In 15 cases of tumor of the spinal canal it was found that in 8 the symptoms were misleading in that they suggested a protruded intervertebral disk. Also during the period when these 15 patients came to operation 100 other patients were subjected to operation for protruded intervertebral disks. In any case of unexplained, intractable root pain and in almost every case in which a protruded intervertebral disk is suspected diagnostic lumbar puncture should be performed and the protein content of the cerebrospinal fluid should be determined. A value for spinal fluid protein of more than 100 mg. per hundred cubic centimeters usually means a neoplasm rather than a protruded intervertebral disk.

Intelligence Following Prefrontal Lobotomy.—Watts and Freeman base their conclusions regarding prefrontal lobotomy on 45 patients observed from six months to seven years after operation. In the patients under discussion it was the emotional charge rather than the peculiar ideas themselves that caused the disability. Before operation only 17 per cent were leading useful lives. At the present time 67 per cent are leading useful lives. The authors present the histories of 2 patients with obsessive compulsive states and of 2 patients with tension states who underwent prefrontal lobotomy. They conclude that pragmatic intelligence is improved by prefrontal lobotomy in persons disabled by obsessive tension states.

renal agenesis are reported. Fourteen of these occurred in a series of 27,000 necropsies at the Los Angeles County Hospital, a ratio of 1 to 1,929. Five were found in a series of 1,831 necropsies at the Huntington Memorial Hospital, an incidence of 1 to 366 necropsies. The ratio for the combined series is 1 case to 1,517 necropsies. Eight clinical cases are reported. In analyzing the 27 unilateral cases the 19 necropsy and 8 clinical cases are considered together. The right and left kidneys were absent with equal frequency. The adrenal gland was present in 17 cases and recorded as absent in none. In 21 cases the ureter and half of the trigone were entirely absent. The solitary kidney was always enlarged unless shrunken by disease. Eleven of the 19 necropsy cases showed congenital defects of the single kidney. In 6 (4 females and 2 males) developmental defects of the genital organs existed. Renal failure was the cause of death in 6 cases. Hypertension had existed in only 3 of the necropsy cases. The study of all kinds of anomalies of the upper urinary tract reveals that there is little hope of distinguishing renal agenesis from renal aplasia clinically with any degree of certainty. Absence of half of the trigone is much more indicative of agenesis than of aplasia. Absence of one ureteral orifice, representation of the orifice by a mere dimple or termination of the ureter just beyond the bladder wall occurs more commonly with renal agenesis than with renal aplasia. However, there are all degrees of ureteral aplasia with renal aplasia.

Management of Uterine Myomas.—According to Phaneuf the treatment of uterine myomas depends on their size, their location in the uterus, their symptomatology and the age of their host. The author reviews the records of 1,000 consecutive cases which he treated. The youngest patient was 20 and the oldest 76 years of age. The incidence of myoma was highest between 30 and 49 years; this observation agrees with other statistics. Women with small myomas which are not productive of symptoms do not require treatment, but they should be kept under observation and examined every six months to a year. Myomectomy, while more difficult of execution than ablation of the uterus, offers a reward in the fact that it prevents castration and also permits many women in the childbearing age, to which it is almost entirely applicable, to gratify their desire for maternity. Even in some who are approaching the menopause, prevention of castration has a salutary influence. For patients to whom myomectomy is not feasible, for those who are the hosts of large tumors and for those who have reached or passed the menopause, hysterectomy has to be considered. A choice must be made from three types of operation—fundic hysterectomy, supracervical or supravaginal hysterectomy and panhysterectomy. The importance of preoperative preparation, of the liberal use of blood and blood plasma transfusions and of postoperative care is stressed. The author reserves radium and x-ray treatment for cases in which surgery is contraindicated because of impaired physical condition and disease of the vital organs, such as the heart, kidneys, liver and lungs, and because of severe hypertension. The mortality in the author's 1,000 cases was 2.8 per cent. No deaths occurred in the last 386 cases. The author prefers surgery to irradiation when the former can be used safely.

Compound Used in Soap to Reduce the Bacterial Flora of Human Skin.—Traub and his collaborators investigated the germicidal action on the skin of hands and forearms of a new synthetic phenol, 2,2'-dihydroxy-3,5,6-3',5',6'-hexachloro-diphenyl-methane, also designated as "G-11." Preliminary studies were made to determine the effect of G-11 on the growth of certain micro-organisms, the sensitivity of the human skin to it and its effect on the bacterial flora of the hands and forearms. Compound G-11 was found to be nonirritating to the skin as judged by more than two hundred patch tests. These were repeated on the same subjects after ten to fourteen days and were again negative. Subjects using 2 per cent G-11 soap regularly for one year have shown no evidence of irritation. The regular use of toilet soap containing compound G-11 in a concentration of 2 per cent reduces the resident bacterial flora of the skin. A person using this soap regularly has a lower resident count after two minutes of washing than a person who washes for twenty minutes with ordinary toilet soap. Thus the

daily use of a soap containing compound G-11 would enable a surgeon or operating room attendant to maintain an extremely low bacterial population on his skin and might permit shortening the routine preoperative scrub-up procedures and perhaps the elimination of irritating germicides without sacrifice of skin cleanliness. The economy suggested by the omission of the alcohol and iodine rinse may be an important factor, especially now when they are not readily obtainable. Regular use of soap containing compound G-11 should reduce the probability of infection following skin abrasions and superficial wounds. This point might be of value in the hygienic care of members of the armed forces. The authors suggest the use of G-11 also in soap or in other vehicles for protection against skin infections from barber shops or beauty parlors, hair follicle infections from cutting oils and the like.

Rh Factor in Obstetrics.—According to Andujar, routine Rh typing is as essential in an obstetric service as A and B determination. Ordinary cross matching, even at 37 C., will not always determine Rh incompatibility. Rh—pregnant or recently delivered women and all newborn infants should be given Rh—blood only. In expected or actual erythroblastosis the infant should receive frequent small transfusions of Rh—group O blood. If any transfusion raises the icterus index, causes "pyrogen" reaction or does not raise the hemoglobin level the Rh factor must be considered as a possible etiologic agent. Every institution should keep an up to date list of Rh—universal (group O) donors available for Rh emergencies.

Vitamin P in Ophthalmology.—Mathewson used vitamin P with satisfactory results in 2 cases of ocular hemorrhage. The first patient had extensive retinal hemorrhages and nasal and bladder hemorrhages, but on giving vitamin P the nasal and bladder hemorrhages ceased, no fresh retinal hemorrhages occurred, and those present became absorbed. He suffered from myelomas, and the nasal hemorrhage was characterized by large blood clots and serum. The second patient had recurrent hemorrhage into the anterior chamber after extraction of a cataract, but on receiving vitamin P there was no recurrence, and the iris, which had become muddy, rapidly cleared. The eye rapidly took on a healthy tone and the patient improved greatly in general appearance and mental agility. It has been suggested (*Am. J. Ophth.* 21:1058 [Sept.] 1938) that deficiency in vitamin C, with consequent defective lens respiration, may be the real cause of cataract, the whole vitamin C metabolism of the body being deranged in this condition. The record does not show that steps were taken to exclude vitamin P, which is apparently often found along with vitamin C in the various natural sources. The evidence in these 2 cases suggests that vitamin P is of value in ophthalmology.

Polio-myelitis in Troops in Middle East: Isolation of Virus from Feces.—Paul and his associates state that polio-myelitis among British troops in the Middle East has not been uncommon since 1940. There were severe and many fatal cases. The virus of polio-myelitis has been isolated from the central nervous system in several of the fatal cases. Attempts were made to isolate polio-myelitis virus from the stools of the patients. The tests attempted to determine (1) their value as a confirmatory diagnostic procedure and (2) whether in these adult cases (which have occurred for the most part sporadically) the virus is harbored in the intestinal tract. The authors examined stool specimens from 35 patients and contacts; 17 of these were American and 18 British. There were 15 cases of typical polio-myelitis, 17 atypical cases and 3 contact cases. From the 10 fatal cases of polio-myelitis the isolation of virus from stools was accomplished in 9 instances. Negative findings have been encountered in the remaining 5 nonfatal cases and in 20 "atypical" cases and contacts. Of the latter 5 were cases of polio-encephalitis, 6 of "acute benign lymphocytic meningitis," 6 of neuritis and 3 polio-myelitis contacts. The negative virus findings do not wholly exclude the possibility of polio-myelitis. These results suggest that the amount of virus present in the intestinal tract was greater in the more severe than in the milder cases, an observation which has not received comment before, and one which may not hold true for juvenile cases. The high percentage of positive results from the fatal cases was probably due to the fact that most of the stools were collected earlier in the disease than in the other polio-myelitis cases. The chances of obtaining positive results are greater during the first than during the later weeks of the disease.

 Oxytocic Drugs and Their Use. C. Moir.—p. 247.

Effect of Posterior Pituitary Fractions on Human Uterus.—Moir points out that, of the two active principles obtainable from the extract of the posterior lobe of the pituitary, one has the property of stimulating the plain muscle of the arteries and certain abdominal viscera; the other is exclusively concerned with the stimulation of the plain muscle of the uterus. It is still a moot point whether these principles exist in the body as separate entities or whether they become these as the result of manipulation of the extract. The vasopressor and oxytocic fractions are sometimes referred to as pitressin and pitocin or as vasopressin and oxytocin. In pitocin and pitressin a substantial separation of the two principles has been effected, but the differentiation is not complete and each contains approximately 10 per cent of the other reckoned in units of respective activity. The author found that the muscular activity of the human uterus varies according to the physiologic state of the organ. In the case of the nonpregnant uterus this is true also with regard to the phase of the menstrual cycle. The response of the uterus to posterior pituitary injection also varies according to the physiologic state of the uterus at the time of the test. Contrary to Knaus's observations, it was found that the nonpregnant uterus responds to posterior pituitary injection at every phase of the menstrual cycle, although response is most powerful immediately before, during or soon after menstruation. The response to posterior pituitary injection during early pregnancy is weak, but it becomes strong if the uterus is already actively aborting its contents. Given in the usual clinical dosage the vasopressor fraction is sometimes a powerful stimulant of the uterus. Conversely, the oxytocic fraction is sometimes without action. The nature of the response to these fractions is governed by the physiologic state of the uterus at the time of the test. The response to posterior pituitary injection by an isolated muscle strip suspended in a saline bath does not necessarily reflect the behavior of the intact uterus to these substances. In particular, an isolated strip of human uterus at term reacts in a substantially different manner toward pitocin and pitressin than does the intact human uterus. The cause of the anomalous behavior is unknown.

Comparative Effects of Sulfonamides in Mild Bacillary Dysentery.—Scadding records observations during the summer of 1943 at a large desert base hospital on the relative efficacy of sulfaguanidine, sulfapyridine and sulfanilamide. Sulfanilamide in heavy doses for forty-eight hours was tried as a routine treatment with results that seemed comparable with those previously obtained with sulfaguanidine. Observations in 358 cases of mild bacillary dysentery demonstrated that sulfanilamide, sulfapyridine and sulfaguanidine in adequate doses are equally beneficial. The only advantage of sulfaguanidine, which has made it the drug of choice, is that it hardly ever has unpleasant side effects. The grave defect of sulfapyridine is its liability to cause serious renal disorders, a special danger in a dehydrating disease, though with adequate

care about water intake this danger should be avoidable. A lesser defect is that it is apt to cause nausea and vomiting. Sulfanilamide in this series had no serious side effects, and its therapeutic possibilities in bacillary dysentery seem to have been unduly neglected.

Plasma in Mumps Epidemic: Hepatitis Following Its Injection.—Beeson and his associates made an attempt to control an epidemic of mumps by passive immunization of susceptible persons. The camp in which their studies were made had a permanent military staff of 500, few of whom had mumps. The epidemic concerned 900 volunteers in training who made up a "young soldiers" regiment and whose average age was 19. New trainees arrived in groups of 70 to 80 each fortnight. Each new group of arrivals was designated as a "troop." The January peak of cases of mumps was due largely to troop 19 (arrived December 11). A member of this troop developed mumps on Dec. 16 and must have been infected before arrival. For the first lot of convalescent plasma (A) 11 convalescents were bled an average of 450 cc. each. All plasma was pooled. For the second lot of plasma (B) 11 other mumps convalescents were bled. The inoculations were given by vein, the A plasma in doses of 4, 5 or 6 cc. to 266 susceptible volunteers at the camp on March 12, and the B plasma in doses of 8 cc. on March 28 to 204 men who had already received the A plasma. There were no reactions. The epidemic was not immediately cut short but declined rapidly. Its decline may have been due to causes other than passive immunization. Cases occurred in inoculated men in the period when they should have been protected, and attack rates on the inoculated men and a control group were not significantly different. Hepatitis developed in 44.7 per cent of the men inoculated. This unfortunate sequel should not of itself condemn the use of passive immunization in the control of epidemics of mumps.

Epidemiology of Hepatitis Following Injection of Mumps Convalescent Plasma.—McFarlan and Chesney state that when 20 cases of jaundice developed among the men who had received mumps convalescent plasma a field survey was made of all the men in training at the camp. Hepatitis developed in 101 of 266 men inoculated with mumps convalescent plasma. In the great majority the onset was between fifty-nine and ninety-four days after inoculation. The authors think it unlikely that syringe transmission was the cause of this outbreak. There was no aggregation of cases in the men of any one troop, such as would have indicated that an agent had been introduced from one recipient and diluted out as the inoculations proceeded. All the 11 donors of the A lot of plasma, which apparently contained the hepatotoxic agent, were questioned. None had ever had jaundice. There was no reason to suppose that the agent was introduced during the processing of the plasma. Two observations indicated that the hepatotoxic agent was probably not the virus of infective hepatitis: First, the interval between the inoculation and the development of symptoms was fifty-nine to ninety-four days in the vast majority of cases, whereas the incubation period of infective hepatitis is from twenty-one to thirty-five days. Second, an attack of infective hepatitis usually confers immunity, but of 11 inoculated men who had had jaundice in childhood 8 developed hepatitis in this outbreak. The incidence in them was higher than the incidence in inoculated men who had not previously had jaundice. The infectivity of cases

of plasma hepatitis was low. A few of the uninoculated men might have been infected by inoculated men who developed hepatitis a month previously, but none of them admitted close contact with a possible infecting case. The most probable explanation of the cases in uninoculated men seemed to be that they were sporadic cases of infective hepatitis. Two late cases in uninoculated men might possibly have been infected by inoculated men who had developed hepatitis at least fifty-seven or forty-nine days previously.

Study of Hepatitis Following Injection of Mumps Convalescent Plasma.—Hawley and his associates made clinical and laboratory observations on 47 patients at the American Red Cross Harvard hospital and on 23 patients never requiring medical attention discovered during a survey of the camp; data were also obtained on 16 more patients who had been admitted to other hospitals before the study was contemplated. The hepatitis was mild and, except for the common skin manifestations and arthralgias, resembled epidemic infective hepatitis as seen among children and young adults in Britain. On the basis of nausea, lassitude, fever and depth of coloration 40 cases were classed as mild, 6 as moderately severe and 1 as severe. The severely involved patient remained in the hospital forty-five days. For comparison with the plasma inoculation hepatitis a table gives the findings in 39 patients with infective hepatitis admitted to the same hospital in 1941-1942. The two groups were fairly similar. The patients with hepatitis from convalescent mumps plasma showed a greater lag in reporting ill, a lower incidence of vomiting and a higher incidence of severe arthralgias and rashes. Laboratory studies which included white cell counts, blood bilirubin determinations and examinations to exclude bacterial infections, Weil's disease and infectious mononucleosis furnished no evidence of a known etiologic agent. Routine cultures of feces, blood and the throat were negative for pathogenic bacteria. Serum agglutinins for *Leptospira icterohaemorrhagiae* and *Leptospira canicola* were absent in 23 persons tested. Heterophil agglutinins (Paul-Bunnell test) were present in only 1 of 38 persons tested in titers above 1:14. This case was diagnosed as infectious mononucleosis. Routine urine examination showed biliruria in all hospital cases. Erythrocyte sedimentation rate was raised in 23 of 39 cases. The leukocyte counts revealed no appreciable differences in the two groups. Liver biopsy material was obtained from 5 patients. The histologic sections in all cases showed varying degrees of hepatitis.

Prevention of Jaundice Resulting from Antisyphilitic Treatment.—Salaman and his associates investigated the hypothesis that jaundice is spread by syringes. A technic of intravenous injection was devised which would exclude the possibility of cross infection. In 67 men treated by the ordinary technic for 120 days the incidence of jaundice was 37 per cent, and in 56 of those treated for 180 days it was 68 per cent. Of 36 men treated by the new technic for 120 days only 1 developed jaundice. Similarly of 18 treated for 180 days only 1 was affected. These results strongly suggest that a causative agent of postarsenical jaundice can be transferred by improperly sterilized syringes and that this transference can be prevented by attention to the technic of injection. It is not implied that infection transferred in this way is the sole cause of the condition; arsenic, or deficiencies of SH (sulfhydryl) containing amino acids in a wartime diet, may still be predisposing factors. Boiling syringes will not necessarily suffice without other precautions. In a busy clinic there are other possibilities of transference of infection against which their technic was designed to guard. Syringes which have been boiled in tap water have to be rinsed in distilled water before use. The gallipot in which the drug is dissolved stands on the bench for long periods and is used over and

over again; the lip of the bottle of sterile water from which it is filled is likely to become contaminated. All these manipulations have to be carried out by attendants who are handling patients and blood stained syringes. There is danger of transference of infection in the course of this procedure even if the syringes are boiled between injections. A closed method obviates these dangers and, once it is organized, is considerably easier and quicker in use than the old open method. There will be occasional cases of jaundice even if the best regulated technic is followed. Some cases of the epidemic type are always likely to occur; moreover the possibility cannot be excluded that arsenic may activate an otherwise healthy carrier.

Epidemiology of Infective Hepatitis.—According to Sheehan it appears fairly clear that jaundice following the injection of neoarsphenamine is not due to the arsenical treatment but is purely due to the transmission of minute quantities of infected blood by unsterilized syringes. The only part played by the neoarsphenamine seems to be that it produces some impairment of liver function in a patient who already has an active hepatitis. The author reviews observations on several groups of syphilitic patients which indicate that sterilized syringes and proper precaution against other contaminations with blood will prevent the development of jaundice which has been observed in high percentages of patients when syringes were merely washed and not sterilized. Further evidence that the neoarsphenamine is not the significant factor comes from the incidence of hepatitis in personnel handling the blood of syphilitic patients in a clinic where many of these patients were incubating hepatitis. Of 85 cases of hepatitis occurring in a sanatorium, the records of 56 were studied in detail. A certain number had been given calcium or gold preparations intravenously, but half of those who developed hepatitis had had no therapy of this kind. None of the patients were given neoarsphenamine, so that this factor can be excluded. The common factor was that every patient had had blood taken from an arm vein for sedimentation rate estimation on admission to the sanatorium and at monthly intervals thereafter. The syringes used for these blood collections were well washed out but not sterilized between 1 patient and the next. The cases of jaundice tended to occur in a ward at monthly intervals corresponding to the monthly intervals between the collection of blood samples. Hepatitis following the administration of neoarsphenamine and that resulting from unsterile syringes used for merely collecting blood appear to be identical with an incubation period of about three months. This is a similar incubation period to that seen in homologous serum jaundice. It is suggested that infective hepatitis in England and in the army in the Mediterranean theater is also the same type of disease and that it could well be transmitted by biting insects.

Thyrogenous Cirrhosis of Liver.—Bickel demonstrated moderate enlargement of the liver in 20 out of 50 patients with hyperthyroidism. The liver edge was smooth, hard and tender. Myocardial insufficiency was present in two thirds of the cases with hyperthyroidism and enlarged liver, while one third did not have any signs of insufficiency. Treatment of hyperthyroidism caused disappearance of liver tenderness and enlargement. These are not instances of a latent cardiac insufficiency but of an active hyperemia. Lesions of the hepatic parenchyma in the course of a thyrotoxicosis are manifested

by a high incidence of functional changes, by icterus of various severity and frequently by a chronic and prolonged course. The stage of hypertrophy of the liver passes into one of cirrhosis, which is often masked by the more evident symptoms of hyperthyroidism and particularly by cardiac insufficiency. The course of this thyroigenous cirrhosis may be a slow one and it may be years before it becomes clinically manifest. Cardiac insufficiency may play a more prominent role in the symptomatology, but the hepatic disorder influences the clinical picture.

- Spontaneous Valvular Pyopneumothorax in Children: Cases. J. M. Pelliza.—p. 420.

Ganglioneuroma.—According to Allende and his collaborators ganglioneuroma of either the abdomen or the thorax is rare in children. The prognosis is favorable if the tumor is removed. They report 2 cases in children of 3 and 9 years respectively. The tumor was located on the left paravertebral region of the abdomen in the first case and on the same side of the thorax in the second case. An erroneous clinical and x-ray diagnosis of sarcoma of the kidney in the first case and of a hydatid cyst of the lung was made. The patients recovered after surgical removal of the tumor, which on microscopic examination proved to be ganglioneuroma. The tumor is made up of differentiated ganglion cells. It may contain either juvenile or embryonal cells, which first are grouped in areas and later assume malignant characteristics. The advisability of an early operation is obvious.

Renal Anaphylaxis.—The subject of Dotta and Delporte's report was given a small dose of sulfanilamide, to which he reacted with anuria and urticaria. The urine (after thirty-six hours of anuria) contained a large amount of hyaline casts but neither blood nor sulfanilamide crystals. The patient had a subcutaneous abscess, which was open late during convalescence. Ten days after he had been discharged from the hospital a new urticarial reaction occurred. This time diuresis was normal. It was found that sulfanilamide powder was applied for the first time to the healing abscess the day on which urticaria reappeared. The authors believe that this case is one of renal anaphylaxis of the Tzank type. This is the first case in the literature in which this form of anaphylaxis was caused by sulfanilamide.

Fulminant Hemoptysis in Bronchopulmonary Cancer.

—According to Crivellari and Giordano fulminant hemoptysis without pulmonary tuberculosis is rare. The authors' patient was a man aged 49 who was normal up to seven months before consultation. The disease began with general debility, cough and occasional small hemoptysis. A tumor appeared at a later date in the right supraclavicular fossa. There were progressive cachexia, loss of voice and dysphagia. Tubercle bacilli were not demonstrated. A clinical and roentgen diagnosis of bronchopulmonary cancer was made. The patient had an acute hemoptysis on the tenth day of hospitalization and died immediately. Necropsy showed bronchopulmonary cancer with metastases to the lungs, paratracheal, intertracheobronchial and hilar lymph nodes, thyroid, liver, adrenals and kidneys.

Book Notices

War Neuroses in North Africa: The Tunisian Campaign (January-May 1943). By Lt. Colonel Roy R. Grinker, M. C., Army Air Forces, and Captain John P. Spiegel, M. C., Army Air Forces. Prepared and Distributed for the Air Surgeon, Army Air Forces, by the Josiah Macy Jr. Foundation. Paper. Pp. 300. New York, 1943.

This preliminary report of the neuropsychiatric casualties encountered during the Tunisian campaign was reproduced and distributed through aid from the Josiah Macy Jr. Foundation. It was written in the theater of operations. In the foreword this fact is given in explanation of the obvious need for careful editing which exists throughout the work.

The material is made up primarily of actual battle casualties which occurred during the difficult campaigns of this period. The authors were stationed from 300 to 500 miles behind the front lines and from 150 to 200 miles behind the active air bases. Patients when evacuated by air arrived for treatment in from two to five days after the breakdown, and others arrived from seven to ten days after the clinical onset. The authors set up a classification scheme of ten clinical syndromes manifested by specific symptoms depending on the manner in which the individual handles the anxiety engendered by his situation. These syndromes are described as "free-floating anxiety, severe and mild," "somatic regression," "psychosomatic visceral disturbances," "conversion symptoms," "depression," "neuroses complicating cerebral concussion," "exhaustion states," "fatigue," "psychoes," and "malingering." Each of these groups is described in some detail and is amply illustrated by case histories. The case histories are interesting and excellently done. One sometimes wishes, however, that the authors had been more complete in their discussion of the conclusion of the case, so that the reader might be more clear concerning the treatment procedures and the outcome. Particularly emphasized is the process of narcoanalysis, which is described as a new type of treatment. It is in essence a new name for a treatment which had been used in a number of psychiatric clinics before the war. This treatment involves the use of short acting barbiturates (sodium pentothal) during which the patient is stimulated to relive his traumatic experience. Some suggestions are made which could well be utilized, however, by civilian psychiatric clinics. Psychotherapy, convulsive shock therapy, continuous sleep treatment, general convalescent care, occupational therapy, group therapy and less discussed methods of treatment are described. The authors give a table and make a general statement concerning the number of patients treated. This is broken down into the number returned to active duty and of those evacuated to the United States and the United Kingdom. This gives the reader a good general overall picture of the value of the treatments utilized but does not answer the question of results in specific cases described in the report. In general the book is very well done, certainly worth while, and has made a genuine contribution to psychiatric war literature. It contains much of value for all psychiatrists, military or otherwise.

Medical Diagnosis: Applied Physical Diagnosis. Edited by Roscoe L. Pullen, A.B., M.D., Instructor in Medicine, Tulane University of Louisiana School of Medicine, New Orleans. With a foreword by John H. Musser, B.S., M.D., F.A.C.P., Professor of Medicine, Tulane University of Louisiana School of Medicine. Cloth. Price, \$10. Pp. 1,106, with 566 illustrations. Philadelphia & London: W. B. Saunders Company, 1941.

According to the editor, Medical Diagnosis emphasizes the methods utilized in the determination of expressions of disease states; these include the history, physical examination and various accessory procedures in the form of endoscopic, roentgenographic and microscopic studies. To accomplish this heroic task 1,042 pages are required. It is evident, therefore, that a thorough inquiry into the subject of medical diagnosis as defined cannot possibly be accomplished between the covers of this book. By and large what is presented is done so in an admirable fashion and will be a real aid to the practicing physician. Worthy of particular mention are the chapters on oral diagnosis, examination of the breast, examination of the chest, examination of the heart, the neurologic examination, and the chapter on determination of prognosis. The electrocardiographic diagnosis is worthy of particular praise, but the reviewer

wonders how well it will be appreciated by the student of physical diagnosis and one wonders why 58 pages are devoted to this aspect of cardiac diagnosis and only some 8 pages to roentgenologic examination; certainly the two are of at least equal value in the diagnosis of heart disease.

It is surprising to find that the various diagnostic procedures indicated in the study of gastrointestinal disease are almost completely ignored, while a total of 39 pages is devoted to urologic diagnosis. The rather important diagnostic value of allergic surveys and of hematologic and feces examinations is not mentioned, while some 10 pages are devoted to a sterility survey and 4 to clinical electroencephalography. The differential diagnosis of coma, which is a problem even for the seasoned clinician, is accomplished in 13 pages. The reviewer feels that this book, although far beyond the grasp of the medical student studying physical diagnosis, will prove of interest to practicing physicians.

A Century of Butler Hospital, 1844-1944. Paper. Pp. 49, with 10 illustrations. Providence, Rhode Island, 1944.

The present volume, written in commemoration of a century of service, is a history of the Butler Hospital, Providence, R. I., from the time of its establishment in 1844. The history is written in three parts dealing with the physical and administrative development, the medical service from 1844 to 1922 and the hospital work under the present medical superintendent. The first section gives an excellent description of the founding of the hospital, its early growth and development, the problems of construction, finance and administration, expansion of services, community interests, humanitarian motives, the loyalty and devotion of administrative and hospital personnel and their constant efforts to enhance the quality of institutional care. Professional service is emphasized in the second part, which describes the work and contribution of the medical superintendents who served Butler Hospital prior to 1922. The final chapter reflects the progress of psychiatric service in the last two decades and gives a clear indication of the role of the modern psychiatric hospital in the expanding fields of mental hygiene, individual health and community health. This volume will be of interest not only to the immediate friends of the institution but to all who are concerned in the problems of psychiatric care.

Experimental Basis for Neurotic Behavior: Origin and Development of Artificially Produced Disturbances of Behavior in Dogs. By W. Horsley Gantt, M.D., Associate in Psychiatry and Head of the Pavlovian Laboratory, Johns Hopkins University, Baltimore. Psychosomatic Medicine Monographs, Volume III, Nos. III and IV. Published with the Sponsorship of the American Society for Research in Psychosomatic Problems. Cloth. Price, \$1.50. Pp. 209, with 52 illustrations. New York & London: Paul B. Hoeber, Inc., 1944.

This monograph is a detailed report of prolonged experiments and observations (in the case of 1 dog twelve years) on some 4 dogs in which disturbance of behavior or neurosis was induced by the conflict and strain method of Pavlov. The report is factual, clear and remarkably free from premature generalizations. The author, a pupil of Pavlov, finds striking and consistent individual variations in the ease of induction, in the extent and in the persistence of the experimentally induced neurosis, including unusual or pathologic sex behavior (erection) in dogs. That the latter should appear under intense or general stimulation of the involuntary nervous system is not surprising, for it has been shown that intense hunger and thirst may induce cooing even in decerebrated pigeons. Experimental neurosis has now been reported in dogs, rats, sheep, hogs and cats. The significant difference in nervous stability of individual dogs will provide useful material for objective and controlled investigation of the complex hereditary factors in nervous instability.

The Analysis and Interpretation of Symptoms. Edited by Cyril M. MacBryde, M.D. [Reprinted from Clinics, Vol. II, No. 6, April 1941.] Fabrikoid. Price, \$1. Pp. 1343-1644, with illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1941.

This book consists of ten articles by ten different authors and an introduction by Dr. MacBryde. The subjects discussed are thoracic pain, cough, abdominal pain, hematemesis and melena, jaundice, joint pains and obesity. From the title of the book one would expect to find a far greater discussion of the underlying causes of the symptoms, such as physiologic and

pathologic data, rather than an outline of simple differential diagnosis. Not that as far as the latter is concerned it has not served its purpose, but so far as strict analysis is concerned it could be improved on in some places. The most important articles are the ones on headaches, mechanisms and differential diagnosis by Harold G. Wolff, abdominal pain by Sara M. Jordan, hematemesis and melena by Leon Schiff, and obesity by Cyril M. MacBryde. Some of the others are fairly good and some are mediocre. It would not be fair to criticize the ability or knowledge of any of the authors, but it is certainly fair to point out the defect of trying to cover too much ground in a limited space. It would be far better to emphasize the commonest cause producing symptoms and indicate them as such than to try to spread oneself over everything pertaining to the subject. The printing is excellent and the index fairly complete.

Health and Medical Care, Washington County, New York. A Study of Resources and Needs for Health and Medical Care in Washington County, New York. Study made by New York State Health Preparedness Commission in Cooperation with Washington County Health Preparedness Committee. Walter S. Bennett, M.D., Chairman. Paper. Pp. 41, with illustrations. New York, 1944.

Health and Medical Care, Ontario County, New York. Resources and Needs for Health and Medical Care in Ontario County, New York. Study made by New York State Health Preparedness Commission in Cooperation with Ontario County Health Preparedness Committee. James S. Allen, M.D., Chairman. Paper. Pp. 48, with illustrations. New York, 1944.

Health and Medical Care, Seneca County, New York. Resources and Needs for Health and Medical Care in Seneca County, New York. Study made by New York State Health Preparedness Commission in Cooperation with Seneca County Health Preparedness Committee. Walter Pamphilon, M.D., Chairman. Paper. Pp. 42, with illustrations. New York, 1944.

These surveys, made by the New York State Health Preparedness Commission, cover three rural and semirural counties. Two (Seneca and Ontario) are in the Finger Lake District, and one (Washington) is on the boundary with Vermont. Much the same picture appears in all three. Allowing for the war arrangements there are adequate physicians but insufficient dentists to provide proper dental care and a pressing shortage of nurses. Where there is a local lack of hospital facilities there are usually additional facilities in nearby counties that can be used.

The indigent are cared for by county arrangements with physicians. Nearly all have some hospital insurance and industrial plans with a variety of coverage, and all consider expenditures for public health too small to provide needed services. The percentage of vaccinations is below the level of the rest of the state and in all three counties immunization for diphtheria is decidedly deficient. School examinations and treatment of defects found are somewhat inadequate but improving. There is a general lack of adequate laboratory services.

The population of these counties contains a larger percentage of persons in the older age groups than the rest of the state. Everywhere there is complaint of a lack of facilities for the chronically ill. The suggestions offered include the development of medical care plans for the indigent, better health education and further study of the localities. Nearly all of the conditions described are highly typical of probably a majority of the counties in the United States not including large cities. The same sort of survey might well be made in other counties as a guide to medical planning.

Electronics; Today and Tomorrow. By John Mills. Cloth. Price, \$2.25. Pp. 178, with illustrations. New York: D. Van Nostrand Company, Inc., 1944.

This is a singularly fine example of popular scientific writing. The nature and properties of the electron are explained, starting from first principles. Electronic phenomena in nature are described with lucidity. The basic experimental studies and types of apparatus underlying the science and applied art of electronics are explained in sequence of development. Finally the means are described through which electronics has grown into the practical arts of television, electron microscopy, communications and control of process and power, and finally of transmutation of matter and energy. The author is experienced both in the science of electronics and in its exposition to lay readers. The volume is a fascinating introduction to a field the applications of which in war and in peace are numerous and superlatively important.

Your Eyes. By Sidney A. Fox, A.B., Sc.M. (Ophth.), M.D., Instructor in Ophthalmology, New York University College of Medicine. Cloth. Price, \$2.75. Pp. 191, with illustrations. New York: Alfred A. Knopf, 1944.

The author has attempted to give in simple language, for the benefit of the layman, a brief description of the eyes and how they function. He discusses the refractive errors and shows how glasses improve vision, clarifies the "bogy man" astigmatism and explains why far sighted persons cannot read without glasses after "old sight" develops. His discussion of color blindness, eye muscles and illumination and his chapter on the eyes in traffic explain why not only vision but good fields, dark adaptation and night vision are important. He attempts to clarify the terms and explain the difference between ophthalmologist, optician and optometrist. The chapter on quacks and panaceas should be given wide publicity. The author explodes for the layman the use of eyedrops to cleanse the eyes or to make them feel better. The chapter on "Young Eyes" stresses the need of an early check on vision and especially the need for early treatment of cross eyes. In the final chapter he discusses chiefly cataracts and glaucoma and devotes much space to the latter. On the whole, the book will serve a useful purpose in acquainting the public with information about the eyes and the need for proper care.

Intracranial Arterial Aneurysms. By Walter E. Dandy, Adjunct Professor of Surgery in The Johns Hopkins University, Baltimore. Cloth. Price, \$2.50. Pp. 147, with 55 illustrations. Ithaca, N. Y.: Comstock Publishing Company, Inc., 1944.

In this monograph Dr. Dandy presents his surgical experience with 64 intracranial aneurysms and a study of the records in 44 other cases in which the lesions were disclosed at necropsy. The pertinent data in 108 cases are presented in the detailed charts appended at the back of the book. The symptomatology, diagnostic details and surgical procedures are clearly and concisely discussed. Each significant point is beautifully and profusely illustrated. The press work is excellent and the publisher is to be congratulated on so splendid a monograph at such a small cost. Every one interested in the diagnosis and treatment of intracranial disease will wish to avail himself of this book. One word of caution: this is not a complete presentation of the subject of intracranial aneurysms. The monograph is written from the surgical point of view. The many patients who develop symptoms either of spontaneous subarachnoid hemorrhage or of local pressure as the result of one of these aneurysms and then recover without surgical intervention have not been presented.

The Neurosurgical Patient: His Problems of Diagnosis and Care. By Carl W. Rand, Clinical Professor of Neurological Surgery, University of Southern California School of Medicine, Los Angeles, California. Cloth. Price, \$4. Pp. 576, with 121 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1944.

This is an interesting presentation of neurologic surgery by one of the foremost neurologic surgeons of the Pacific Coast. It has been prepared for students and is in the form of clinic or classroom presentations. It is largely an expression of the personal views and experiences of Dr. Rand rather than a survey of the various opinions held by the neurosurgical profession. Students and practitioners alike will find this a valuable book in which a sound conservative point of view is presented. Dr. Rand's neurosurgical colleagues will welcome this opportunity to share in his views and experience.

Toxicity and Potential Dangers of Penta-Erythritol-Tetranitrate (PETN). By W. F. von Oettingen, Principal Industrial Toxicologist, and others. From the Industrial Hygiene Research Laboratory, National Institute of Health. Prepared by direction of the Surgeon General, Federal Security Agency, U. S. Public Health Service. Public Health Bulletin No. 282. Paper. Price, 10 cents. Pp. 39, with 9 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1944.

These statements, originally made as confidential reports to the Ordnance Department of the U. S. Army, are now issued for general information. It is concluded that penta-erythritol-tetranitrate, otherwise known as penthrite, is relatively nontoxic. Nitrite effects are produced by large doses, but unusual exposure can be readily controlled by ordinary good housekeeping and personal hygiene. The pamphlet contains much useful information about the chemistry and toxicology of the aliphatic nitrate esters.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TESTOSTERONE PROPIONATE FOR ANGINA PECTORIS

To the Editor:—I am interested in testosterone propionate for its effect on angina pectoris. There was an article in *The Journal* not long ago that discussed this treatment, but I should like to have further information regarding not only its effectiveness but also its contraindications more specifically than was given in the article. Information as to its beneficial effects on senility would be welcome, of course, but the thing that I am particularly interested in would be the possibility of dilatation of the coronary vessels and their increased supply of blood to the heart. What would be the effect of the use of this hormone on becoming easily fatigued and on insomnia?

Charles J. Adams, M.D., Kokomo, Ind.

ANSWER.—The consensus of recent clinical reports seems to be that sex hormone therapy exerts a favorable effect on symptoms if not on the course of angina pectoris. Thus, Strong and Wallace (*Canad. M. A. J.* 50:30 [Jan.] 1944) report great improvement in 6, slight to moderate improvement in 11 and no effect on 3 patients with angina pectoris. Walker (*J. Clin. Endocrinol.* 2:9 [Sept.] 1942) noted definite improvement in 7 of 9 patients with coronary disease when treated with testosterone propionate. The response was manifested by an increase in tolerance to all precipitating factors, an increase in strength and in some cases considerable decrease in the severity of pain when attacks occurred. Sigler and Tulgan (*New York State J. Med.* 43:1424 [Aug. 1] 1943) report symptomatic relief in 11, less pronounced relief in 5 and no relief in 4. Lesser (*New England J. Med.* 228:185 [Feb. 11] 1943), in reporting the results of treating 46 patients with angina pectoris, states that no untoward effects from the use of testosterone propionate were noted and that its beneficial effects continued from two to twelve months after treatment was withdrawn. In the majority of cases there was a lowering of blood pressure levels during the therapy. All his patients showed improvement. Four were studied by means of the exercise tolerance test before and during the course of therapy to obtain quantitative measurements of improvement. In each the amount of exercise tolerated before the development of anginal attack was increased under testosterone therapy, and the severity of the attacks, as measured by the duration of pain, was correspondingly diminished. When sesame was substituted for testosterone these results could not be duplicated. Hamum (*J. Clin. Endocrinol.* 2:325 [May] 1942) did not note unfavorable effects from sex hormone therapy. Average dosage consisted of thirty injections of 25 mg. doses of testosterone propionate in twelve months. There was a general improvement in mental and physical endurance and relief from angina pectoris in all of his 7 patients. This symptom free state lasted for six months in some cases and for eleven and a half months in others. Bonnell and his co-workers (*Ohio State M. J.* 37:554 [June] 1941) recorded clinical improvement in 22 of 23 patients. They believe that the improvement is due to a vasodilating property of sex hormones acting on the coronary circulation. They review the experimental evidence that estrogens and androgens in some manner cause vasodilatation. Thus there seems to be a unanimity of opinion as to the beneficial effects on the subjective symptoms of coronary disease. Although it is difficult to eliminate the psychic effect of the treatment, it would appear that the pharmacodynamic effect of the sex hormone cannot be ruled out. The only dissenting report is that of Levine and Likoff (*New England J. Med.* 229:770 [Nov. 18] 1943). Of 18 patients treated by them 5 showed improvement, 11 were not improved and 2 were only questionably improved. These authors were unable to conclude that testosterone propionate had any beneficial effect.

CARE OF PATIENTS AFTER REMOVAL OF CATARACTS

To the Editor:—What is the accepted postoperative treatment of cataracts, particularly the nursing care? Do cataracts require special aid by nurses or attendants? What should the procedure be in a government institution? The question has arisen for discussion from the administrative point of view.

M.D., Florida.

ANSWER.—Every ophthalmic surgeon of experience has his own views on the postoperative care of cataract patients, with the result that there is no established uniformity of procedure. Before the present shortage of nurses existed it was thought

that each patient should have private nursing care when possible, but now it appears that the eyes are just as good under general floor nursing care, a procedure that can be utilized in governmental institutions as well as in private hospitals.

In general, the following orders cover the after-care recommended by the majority of ophthalmic surgeons: 1. Absolute bed rest for three to five days; for the first twelve hours the patient should be on his back but then may be turned to the unoperated side and propped with pillows. The back rest may be up one, two or three notches according to desire. A head pillow is permitted. The prone position should be avoided unless requested by the patient. According to the surgeon and the progress of wound healing, the patient may be assisted into a chair on the third to the fifth day and stay up as long as desired. No walking should be permitted before the seventh day. The average stay in the hospital is ten to fourteen days. 2. A liquid diet is advised for the first forty-eight hours, a soft diet for the next five days and a nonchewy diet for the remainder. 3. An enema may be given on the third day if necessary. The patient must be fed by nurses while both eyes are bandaged. Subsequently liquid petrolatum or enemas may be used as necessary. 4. No bathing for three days, then sponge baths in bed. 5. No visitors for three days. 6. Sedatives at bedtime for three days—after that, as required. 7. Dressing of the eyes is performed only by the surgeon. A protective mask is to be worn and kept in position at all times. In general, these orders cover the requirements for postcataract care but have to be modified according to the exigencies of each case.

PROTECTION AGAINST HARMFUL SUNLIGHT

To the Editor:—For the past two years I have been afflicted with a sensitivity to sunlight which causes a rash on my face, diagnosed as a potential lupus erythematosus. On exposure to ultraviolet rays the rash did not appear, so it can be assumed that those wavelengths are not responsible. Porphyrin bodies have not been found in the urine. I have been experimenting with a mask of cellophane and with protective ointments. Would you please inform me as to the various ointments used and of any similar mask which has proved effective, and how the latter could be obtained?

Captain, M. C., A. U. S.

ANSWER.—Information on cellophane or other masks has not been obtained. Most plastics have no value for the exclusion of light. The claims made for various invisible oils or ointments as protection against light have not been substantiated by careful experiment. Strakosch, for instance (*The Role of Bases in Ointments Used for Protection Against Sunlight, J. Invest. Dermat.* 5:1 [Feb.] 1942), found that neither petrolatum nor lanolin gave any protection in thin layers. He thinks that Raabe's claim for yellow petrolatum was based on the use of a thick layer. The addition of quinine or tannic acid to these bases added no protective effect; but with aquaphor and Abbott's Ninol base they did add to the protective action. Epstein (*Studies in Abnormal Human Sensitivity to Light, J. Invest. Dermat.* 5:187 [Aug.] 1942) reports that some of his patients obtained benefit from ointments containing tannic acid or resorcinol.

The best protection from light should be obtained from preparations impervious to light, such as zinc paste or modifications of it. Fantus and Dyniewicz (*Cuticolar Preparations, J. Am. Pharm. A.* 27:878 [Oct.] 1938) proposed an improvement on calamine powder consisting of zinc oxide or, better, titanium dioxide, colored with a mixture of the red and yellow oxides of iron, with blood charcoal to darken it to correspond to brunette complexions. They used red ferric oxide 3 Gm., yellow ferric oxide 4 Gm. and zinc oxide 93 Gm. or, for a better covering preparation, red ferric oxide 6 Gm., yellow ferric oxide 8 Gm. and titanium dioxide 86 Gm. They remark "Should clinical trial justify the greater expense, it may become desirable to employ the titanium dioxide instead of the zinc oxide in all these preparations. We find the titanium dioxide a necessary ingredient of the cuticolar cream salve that may be used for covering skin blemishes." The formula of this is cuticolar titanium dioxide 30 Gm., glycerin 1.5 cc. and vanishing cream 70 Gm. Mix thoroughly. With different lots of the pigments, the proportions must be varied and, of course, are variable to suit different complexions. If desired, the cuticolar powder may be used in a lotion, suspending 15 Gm. in 100 cc. of rose water in which 2.5 Gm. of bentonite has been suspended. The bentonite suspension should stand for several hours and the supernatant fluid be decanted to get rid of any larger particles. Then add the cuticolar powder to the decanted portion. A greaseless paste may be made by rubbing up cuticolar powder 15 Gm. and bentonite (sifted) 10 Gm. with rose water 75 cc.

Epstein mentions a case of prurigo estivalis that cleared after a course of histaminase, while others did not, and quotes O'Leary, who also had good results from histamine desensitization and from histaminase. Epstein remarks that tarantil,

a preparation of histaminase, varies in strength, which may account for the discrepancies in results.

Civatte, Tzanck and Sidi (*Bull. Soc. franç. de dermat. et syph.* 46:1344 [Sept.-Oct.] 1939), whose article is abstracted in the *Archives of Dermatology and Syphilology* 43:855 (May) 1941, obtained benefit in cases of lupus erythematosus by medication with niacin amide, apparently causing a suspension of sensitivity. Keining (Untersuchungen über das Indikationsgebiet des PP-Faktors [Nikotinsäureamid] bei Hautkrankheiten, *Dermat. Wchnschr.* 112:302 [April 12] 1941) reports success in the treatment of some cases of lupus erythematosus-like eruptions evidently sensitive to light, for they recurred early in spring, by a few daily injections of niacin amide. In 1 case a slight recurrence in the fall yielded again to the injections. In a case of "summer eruption" the action was slower, and in some cases of lupus erythematosus there was no benefit.

It is suggested that, if resorcinol or quinine is tried, the skin be patch tested first to guard against the possibility of sensitization to these drugs, both of which are notorious allergens.

VARICOSE ULCERS

To the Editor:—A woman aged 49, who weighs about 250 pounds (113 Kg.), has had considerable trouble with varicose veins and ulcers on her legs from the knee to the ankle since her last confinement thirteen years ago. She has had various treatments with intravenous sclerosing agents, but not the McPheters operation of opening the vein in Scarpa's triangle. Now the leg from the knee to the ankle is a deep purple and has the feeling of dead tissue. When she bumps it there is an open sore, which is slow in healing. Her urine and blood pressure are normal. She has consulted me in regard to the use of the new drug tyrothricin in her case.

M.D., Missouri.

ANSWER.—The state of venous circulation must be first investigated by suitable tests. These have been described and illustrated by a pamphlet on varicose veins published by the American Medical Association and reprinted in 1941. If the deep venous circulation is impaired, neither ligation nor sclerosing injections can help; in fact, such procedures may aggravate the circulatory insufficiency. Thrombophlebitic ulcerations heal slowly, not only because of venous stasis, but because they are often surrounded by a collar of fibrous, avascular tissue which interferes with tissue repair. Secondary infection with aerobic and anaerobic bacteria often aggravates the picture.

Tyrothricin is the name applied by Hotchkiss and Dubos to an alcohol soluble and water insoluble fraction which is obtained from a culture of aerobic sporulating bacilli found in soil. This is not a pure substance and two crystalline materials, tyrocidin and gramicidin, have been separated out. Tyrocidin is essentially ineffective in the living tissue, since serum and tissue juice inhibit its action to a considerable degree. Gramicidin, on the other hand, is highly effective when applied locally against gram positive organisms such as pneumococci, streptococci, staphylococci and diphtheria bacilli. It is not particularly valuable in mixed infections and cannot exert much effect when the circulation is poor.

In the case under consideration, if a bacteriologic study yields gram positive organisms and if the circulation can be improved by adequate elevation and fomentation, a local application of gramicidin might be of help. It will combat only the superimposed infection of a thrombophlebitic ulcer and will not remove its cause or inhibit its recurrence.

SULFONAMIDE THERAPY FOR PATIENTS ON RESTRICTED SODIUM DIETS

To the Editor:—When using sulfonamides it is frequently necessary to administer alkalis. This raises a problem in connection with patients who are on restricted sodium diets; for example, those with cardiac edema and toxemias of pregnancy. What is the solution to this complication?

Robert C. Tavlin, M.D., Chicago.

ANSWER.—The prevention of kidney complications in patients receiving the sulfonamides is greatly aided by alkalization of the urine and the maintenance of an adequate fluid balance. In patients with edema, particularly those whose edema is due to cardiac failure or renal dysfunction associated with nitrogen retention, the problem is not readily solved. In cardiac failure it is often necessary to restrict fluids unless the patient can be maintained on a dietary regimen in which the intake of sodium is restricted to less than 1 Gm. of sodium chloride a day. In addition, sodium salts should not be given to alkalinize the urine. While potassium salts may be used, they must be given with due caution to patients having renal dysfunction, and especially to persons having uremia. However, this is one solution to the problem. Another possibility is to reduce the total dose of the sulfonamides to a minimum. In other words, relatively small doses of a sulfonamide are necessary for the treatment of a

urinary tract infection. It should be remembered that sulfanilamide rarely if at all causes kidney complications, and several types of pyogenic infections may be treated with this drug. With more and more penicillin being made available for civilian distribution, this material may be used instead of the sulfonamides in conditions in which it is indicated.

ALKALIZATION BY PARENTERAL ROUTE

To the Editor:—Can you give me a plan for administering alkalis parenterally? Specifically, how much (and of which preparation) should be given intravenously to render the urine alkaline when the oral route is not available—particularly when sulfonamides are being used?

Robert C. Tavlin, M.D., Chicago.

ANSWER.—Alkalization of the urine by parenteral administration is accomplished by supplying an excess of basic ions. This can be accomplished with sodium lactate or sodium bicarbonate, the lactate or bicarbonate radical being metabolized in the body, thus leaving an excess of sodium ion. Sodium lactate is usually preferred, as it is less strongly alkaline than sodium bicarbonate. Sodium lactate can be obtained in a sixth molar concentration commercially for intravenous use. The concentration is isotonic. Gilligan, Garb and Wheeler reported that during administration of sulfadiazine 15.6 Gm. of sodium bicarbonate orally was adequate to render the urine consistently alkaline. With a dosage of 13.7 Gm. of sodium bicarbonate 15 per cent of the patients had acid urine. One hundred cc. of sixth molar sodium lactate is equivalent to 1.4 Gm. of sodium bicarbonate. Therefore 1,100 cc. of sixth molar sodium lactate solution is equivalent to 15.6 Gm. of sodium bicarbonate. In 2 of the cases reported by Gilligan, Garb and Wheeler 1,000 cc. of sixth molar sodium lactate was given intravenously in divided doses daily, and the urine remained alkaline. They advised continuing the alkali for one day after discontinuing the sulfonamide.

DRUGS CAUSING APLASTIC ANEMIA

To the Editor:—At present in our hospital there is a soldier with aplastic anemia. The only medication prior to the discovery of this condition was elixir of terpin hydrate with codeine (0.008 Gm. in 4 cc.), acetylsalicylic acid and castor oil (15 cc.). The question is: Can this medication cause a depression in the function of the bone marrow? If so, which one, and can authorities be cited?

Crofton, M. C., A. U. S.

ANSWER.—Although it is well known that certain drugs may so depress the function of the bone marrow as to produce aplastic anemia, this drug has never been mentioned, i. e. elixir of terpin hydrate. There is no evidence that codeine, acetylsalicylic or castor oil is capable of this effect. According to present knowledge, the only drugs capable of depressing the function of the bone marrow include those that have the benzene ring as their central structure.

COITUS RESERVATUS

To the Editor:—There seems to be some controversy as to the merits and demerits of the practice of coitus reservatus. I cannot find any agreement on the matter; in fact there seems to be little of a reliable nature published on the subject. I wish to know especially whether the practice is harmful from the point of view of possible harm to the prostate gland, i. e., would it tend over a long period to produce chronic congestion and resultant troubles? What effect would age be apt to have on such a practice? Anything of a scientific nature or anything in the way of opinion, even, if given by a qualified person, will be greatly appreciated.

M.D., Maine.

ANSWER.—It is thought that the practice of coitus reservatus produces a congestion in the region of the posterior urethra which may possibly predispose to a prostatitis. There is no evidence that age would have any effect on such a practice except as coitus itself is limited by the two extremes of life.

PINWORMS AND TAPEWORMS IN DOGS

To the Editor:—I am writing for information concerning dogs and pinworms. Can and do human beings have the same type and strain of pinworms as dogs? Are there any injections that can be given to dogs to immunize against pinworms? Can human beings be infected by contact with dogs or their excreta?

S. T. Rogers, M.D., New Albany, Ind.

ANSWER.—Dogs do not suffer from pinworm infection. The tapeworm segments which dogs pass simulate pinworms, but on close inspection of a fresh specimen the difference will be readily noted. According to published opinions the chances for infecting human beings with tapeworm segments are remote.

HYPOGLYCEMIA AND RESTORATION WITH GLUCOSE

CHAIRMAN'S ADDRESS

FRANK C. MANN, M.D.

ROCHESTER, MINN. .

It has been known for almost a century that the concentration of the sugar in the blood might under certain conditions decrease to a very low value, but it has been only a little more than two decades since it was learned that a characteristic group of symptoms followed by death developed in hypoglycemia and that the administration of suitable amounts of glucose would restore the moribund organism in hypoglycemia to normal. The concomitant development of the characteristic symptoms associated with hypoglycemia and the restoration of the dying organism to a quick and complete recovery by glucose are not only among the most dramatic but also some of the most constant biologic phenomena noted in the higher forms of animals. It is my purpose in this paper to present briefly the current knowledge concerning these two physiologic processes which has been obtained from a review and evaluation of the results of a large number of investigations.

It has been conclusively demonstrated that a constant supply of glucose is essential for life in the higher organisms. If the glucose content of the blood decreases below a minimal value, death invariably occurs. Since the sources of glucose available in nature are many, varied and usually not in the form of the substance itself, elaborate physiologic mechanisms are necessary to insure a constant supply of this vital substance to the tissues of the body. The gastrointestinal tract affords the means by which glucose is obtained for the organism from the crude substances in which the sugar occurs or from which it can be made. The rate at which glucose enters the body from the intestinal tract is variable. There is a plethora of glucose during the time of absorption from the alimentary tract and a deficiency between periods of feeding. In order to maintain a life sustaining amount of glucose in the blood a regulatory mechanism within the body is absolutely essential. The maintenance of the sugar content of the blood is a physiologic responsibility of the liver.

The exact mechanisms involved in the maintenance of the blood sugar values under the varying physiologic requirements for glucose are not fully understood, but

it has been definitely proved that the liver is essential. The liver has been removed from a large number of animals including representatives of several species. In no instance has the blood sugar failed to decrease in the dehepated animal and in no instance has there been a restoration of the blood sugar after removal of the liver except as a result of the administration of glucose or substances from which glucose could readily be made within the liverless body. The liver is necessary for maintaining the concentration of sugar of the blood, and compensation for loss of this hepatic function can be made only by the artificial administration of glucose. The evidence would indicate conclusively that the liver is always either directly or indirectly involved in hypoglycemia.

The function of the liver of supplying glucose to the blood depends on the ability and capacity of the hepatic tissue for storing and making glucose. Glucose is stored in the liver in the form of glycogen and made by the hepatic cells from a large number of substances. It has been shown that glycogen is made from glucose when the concentration of the sugar in the blood reaching the liver is above the physiologic level being maintained at that particular time. The liver makes glucose and glycogen from the other carbohydrate substances that are absorbed from the intestine. The liver also makes glucose from noncarbohydrate foodstuffs. Carbohydrate can be derived from both protein and the glycerol fraction of fat. The processes whereby these noncarbohydrate substances are made into glucose and glycogen occur mainly, if not wholly, in the liver. Certain intermediary metabolites of extrahepatic tissues are converted into glycogen by the hepatic tissue.

Glycogen is found in many tissues of the body besides the liver. The total amount of glycogen in the muscle tissue exceeds the amount in the liver. Tissues other than the liver and muscle normally contain only small amounts of glycogen. The evidence would indicate that the enzymes in the extrahepatic tissues which contain glycogen convert it into substances other than glucose. It has been proved that glycogen in the muscle does not give origin to blood sugar and it has not been proved that the sugar of the blood can originate from the glycogen found in tissues other than the liver. Likewise the existing evidence indicates that only small amounts of glucose can be made from other substances in tissues outside the liver. While it cannot be stated that extrahepatic tissues do not aid the liver in the maintenance of the blood sugar either by a glycogen stage or by the direct formation of glucose, such aid must be very feeble. The fact that fatal hypoglycemia always follows removal of the liver is sufficient proof that, if extrahepatic sources of blood sugar exist, they

From the Division of Experimental Medicine, Mayo Foundation.
Read before the Section on Pathology and Physiology at the Ninety-fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

are totally incapable of supplying the needs of the body for glucose.

Restoration in hypoglycemia is specific for glucose. Conclusive proof for this statement is derived from observations on the dehepatized animal because, when the liver is present, partial restoration of the blood sugar in hypoglycemia can be brought about by the administration of substances which stimulate the liver to secrete sugar into the blood. A very large number of substances have been injected into dehepatized animals in hypoglycemia for the purpose of resuscitation. The results of these experiments are very definite and conclusive. The dehepatized animal in hypoglycemia is restored to normal only by glucose or substances from which glucose can be made in the tissues of the body outside the liver. All substances used to date, with the exception of glucose and those substances that can be converted to glucose extrahepatically, have proved to be ineffectual in the prevention of death of the hypoglycemic, liverless animal. These two facts, (1) that a lack of glucose in the blood causes death and (2) that glucose alone is specific for restoration in hypoglycemia, prove conclusively that a minimal amount of glucose is required and is constantly being utilized in some manner by the animal organism during life.

A decrease of the concentration of blood sugar to values which are followed by symptoms and death may be due to many causes. Hypoglycemia may be due to the following general causes: (1) utilization of glucose faster than it can be supplied, (2) dearth of glucose and substances from which glucose can be made, (3) failure of the intrinsic hepatic mechanisms for storage, synthesis or secretion of glucose or (4) primary hepatic insufficiency. Since most of the glucose supplied to the body is utilized in the extrahepatic tissues, anhepatic processes may profoundly alter the rate at which glucose is withdrawn from the blood. Certain anhepatic processes are also essential for providing the hepatic tissues with some of the substances from which glucose is made within the liver. The intrinsic hepatic mechanism for providing glucose for the body is affected by substances produced in extrahepatic tissues. Primary hepatic insufficiency may cause hypoglycemia, but it should be noted that only a small percentage of the normal amount of hepatic tissue is required for the maintenance of the normal blood sugar values.

There are numerous anhepatic substances and processes which are of fundamental importance in regard to the maintenance of the concentration of glucose in the blood. Among these, certain endocrine substances and types of metabolism are of great significance. In most instances, in spite of a vast amount of creditable research, agreement is lacking in regard to the mechanisms whereby the various hormones affect the blood sugar. An interesting chapter in physiology will have been written when the various phases of these mechanisms have been conclusively demonstrated. There is a considerable bulk of evidence which indicates that the type of food being utilized in preponderance in the extrahepatic tissues greatly alters the mechanism for control of the blood sugar.

Several interesting hypotheses have been developed in explanation of the cause of the symptoms in hypoglycemia. The data obtained for the support of these hypotheses have been of considerable value in clarifying certain phases of the phenomenon. Since the major symptoms of hypoglycemia indicate that the functions

of the nervous system are primarily affected and since glucose is very important in metabolism, the more pertinent investigations on the cause of the symptoms of hypoglycemia have dealt with the metabolism of the brain.

A considerable amount of evidence has been accumulated from various sources which indicates that glucose is the main if not the only source of energy for the brain. The results of a number of investigations on the oxygen consumption and carbon dioxide production of brain tissue *in vivo* agree in general that the oxygen consumption is high and that the respiratory quotient is usually about unity. The results of studies on the metabolism of slices of brain tissue are in accord with those of the studies of the brain tissue *in vivo*. While the results of none of these investigations, because of the possibility of error owing to the methods that had to be used, should be accepted without qualification and in spite of the fact that a serious error was made in regarding glucose as the only source of energy for muscular contraction, it would appear highly probable that the brain obtains, at the least, most of its energy from the combustion of carbohydrate.

The results of investigation of the metabolism of the brain in hypoglycemia as well as the results of studies on the interrelation between anoxia, asphyxia and hypoglycemia indicate that the oxidative metabolism of the brain is diminished in hypoglycemia. This finding provides an explanation for the sequence of the development of the symptoms of hypoglycemia. The decrease of blood sugar affects various regions of the brain successively, beginning with the cerebral hemispheres and ending with the vital centers in the medulla. This definite order of the symptoms is predicated on the basis that the lack of glucose affects the brain cells having the highest rate of metabolism first. In this connection it should be noted that other factors are also involved because the symptoms of hypoglycemia may develop, under certain conditions, at a blood sugar value which, though decreased from its immediate previous value, is above the normal level.

The mechanism whereby hypoglycemia causes death and the action of glucose in producing restoration remain as important and only partially solved problems. It was noted in the first experiments on the dehepatized animal in which hypoglycemia was recognized as a cause of death that the respiration always stopped before the heart. It is usually possible to restore the animal in hypoglycemia after respiration has ceased by the application of artificial respiration while injecting glucose. As previously mentioned, all the major symptoms that appear in hypoglycemia can be referred to functional alterations in the central nervous system. The discernible effect of glucose is to restore the functional activity of the brain. These facts would appear to prove that the central nervous system constantly requires the presence of glucose in order to function. It is not so evident that other tissues also require glucose to maintain life. In this connection it should be noted that isolated organs as well as isolated tissues are often studied under a condition of hypoglycemia. Some of the functions of perfused organs appear to be performed normally in the absence of glucose in the perfusate or the organ itself. It would appear that life and function can be maintained in some tissues without glucose.

While the discovery that a certain concentration of glucose in the blood is essential for life was made on the dehepatized animal, most of the facts that are known about the effects of a low blood sugar on the various physiologic activities of the body have been learned through the use of insulin because it is easier to produce hypoglycemia with insulin than by any other known method. The results of studies on hypoglycemia produced by removal of the liver and the injection of insulin have been mutually corroborative. It would appear that the cause of the symptoms and death in hypoglycemia is the same regardless of the mechanism producing the decrease of blood sugar. However, there is one great difference between the restoration of the organism in hypoglycemia due to removal of the liver and in that due to other causes. While glucose is effective in restoring the hypoglycemic organism to normal, provided the lack of glucose has not persisted for too long a period, regardless of the cause of the hypoglycemia, in the absence of the liver the period of restoration is only temporary while in the presence of the liver it is permanent or persists until the causative agent is again active. A permanent recovery from hypoglycemia always depends on hepatic activity.

Since the presence of the liver has remained as a possible source of error in the interpretation of the results of studies on hypoglycemia produced by extrahepatic causes, my colleagues and I have recently attempted to develop a method for the study of a preparation which not only is practically glucose free but also is incapable of receiving glucose except by administration. The objective of the research was to attempt to maintain artificially those functions of the body loss of which, owing to the hypoglycemia, appeared to be the cause of death and thus determine the physiologic activities that would persist in the absence of glucose.

Briefly the method is as follows: The liver is removed in the usual manner. When the animal exhibits the first symptoms of hypoglycemia, the trachea is intubated and respiration is maintained artificially after spontaneous respiratory movements cease. Transfusions of whole blood are given to aid in supporting blood pressure.

While progress has not been made toward our major objectives, some pertinent findings have been noted. Blood pressure progressively decreases as the animal becomes flaccid in hypoglycemia, and the central vasomotor mechanism ceases to function shortly after respiratory movements stop. While it is easy to substitute for the lost respiratory function, it has so far been impossible to restore blood pressure, although we have been able to maintain it at a very low level for a few hours. The transfusion of whole blood will increase blood pressure for short periods, but even the injection of very large amounts of blood, more than the estimated total amount of the animal's blood volume, will restore blood pressure for only a short period. The very small amount of glucose in the blood appears to be more effective in increasing the blood pressure than the increase of blood volume.

Cardiac action and a low blood pressure have been maintained for several hours after respiratory movements had ceased. The reducible substances in the blood were at very low values, indicating that the organism was practically glucose free. No evidence of

activity of the central nervous system could be detected. The injection of glucose restored respiration and partially restored blood pressure, many of the reflexes returned and uncoordinated movements occurred. However, there was no evidence of return of cerebral function.

SUMMARY

The maintenance of a definite concentration of glucose in the blood is a physiologic constant. If the blood sugar decreases below a certain critical level, definite and characteristic symptoms appear, followed by death. The physiologic responsibility for maintaining a life supporting amount of glucose in the blood belongs to the liver, but many extrahepatic factors and mechanisms cause variations of the blood sugar to occur. The major symptoms and death in hypoglycemia are due to the effect of the lack of an adequate amount of glucose for the central nervous system, which requires the presence of glucose in order to function. Glucose is essential for life in the higher organisms and appears to be as irreplaceable as oxygen.

FIBRIN FOAM AS A HEMOSTATIC AGENT IN REHABILITATION NEUROSURGERY

MAJOR BARNES WOODHALL

MEDICAL CORPS, ARMY OF THE UNITED STATES

The introduction by Ingraham and Bailey¹ of fibrin foam² as a hemostatic agent in neurologic surgery marks a technical advance as significant as the earlier introductions of the silver clip and the electrocautery. The control of hemorrhage from small or moderate sized vessels in the brain or spinal neuroaxis by electrocoagulation or clipping is relatively standardized and has been proved satisfactory. The control of capillary bleeding from the substance of the brain or spinal cord, from small vessels over the surface of the medulla or spinal cord or from the vascular supply of peripheral nerves cannot be accomplished by these destructive measures. Nor is it feasible to control gross hemorrhage from tumor beds or lacerated venous sinuses by these techniques. For these purposes, cotton patties soaked in warm saline solution or muscle stamps have been used. As Ingraham has pointed out, everyday experience has indicated that these methods may be both time consuming and ineffectual in securing complete hemostasis and, in addition, the use of muscle may be followed by considerable tissue reaction.

Ingraham has recounted the history of the search for an adsorbable hemostatic agent culminating in that prepared from material entirely of human origin by Bering.³ In the same paper microscopic studies in

animals and further clinical and microscopic studies in 95 neurosurgical procedures in man have established the present hemostatic value of fibrin foam and the negligible tissue reaction incident to its use. Through the courtesy of Dr. Franc Ingraham and the members of the Department of Physical Chemistry of Harvard Medical School, fibrin foam was made available to the Neurosurgical Section of the Walter Reed General Hospital in the fall of 1943. Since Jan. 1, 1944 increased production of this substance has allowed its use in a total number of 226 neurosurgical operations. The general character of the diagnoses for which these operations were performed are listed in the accompanying table.

These cases do not represent a valid numerical cross section of material commonly treated in an Army Neurosurgical Center, nor do they indicate necessarily procedures in which there exists a definite need for fibrin foam as a hemostatic agent. They do represent a group of neurosurgical operations in which the value of fibrin foam was explored or in which it was used for some specific technical purpose in which complete hemostasis was desirable. The field of rehabilitation or reparative military neurosurgery is a restricted one. Its paramount task lies in the treatment of nerve injuries

Neurosurgical Operations in Which Fibrin Foam Was Used

by the procedures of neurolysis, neurorrhaphy or nerve grafting. Next in importance is the evaluation of the sequelae of head injuries and, in particular, the repair of skull defects and associated pathologic changes in the dura and brain. In addition to actual war casualties, the military neurosurgeon in the zone of the interior must treat casual illness and injury among military personnel, and of these the most important from the point of view of numbers is that of rupture of an intervertebral disk. Finally, to the Neurosurgical Center gravitate cerebral and spinal cord tumors. Acute cerebral injuries are comparatively rare.

It is apparent then that specific problems in hemostasis may arise in this restricted but, at the moment, important field of neurosurgery. They may be listed as the control of hemorrhage from extrinsic nerve scar, from nerve ends prepared for suture or grafting, from repair of dural or cerebral cicatrices, from extradural spinal veins and finally from tumor beds. It seems obvious that such experience may be transposed readily to the neurosurgery of more active theaters. The characteristics and clinical usage of fibrin foam may be illustrated best by comment on individual cases:

CASE 1.—Rupture of an intervertebral disk. Hemilaminectomy. Reexploration.

E. D. B., T/5, aged 31, developed the classic symptoms and signs of a rupture of the intervertebral disk at the fifth lumbar interspace on the left side, and the diagnosis was confirmed by pantopaque myelography.

On March 1, 1944, after resection of the ligamentum flavum at the fifth lumbar interspace on the left side, a large herniated nucleus pulposus was removed. Prior to removal the extradural veins had been collapsed by cotton patties. When these patties were lifted from the operative field a vigorous venous hemorrhage ensued. After the point of bleeding had been cleared with suction, a small, irregular mass of fibrin foam was applied over the bleeding area and gently compressed with a moist saline pledget. The hemorrhage ceased at once. The nerve root was allowed to assume its normal position and was covered with several additional masses of fibrin foam, filling the interlaminar defect. A severe contralateral sciatica developed and on March 21 the operative area was reexplored in the course of its relief. The fibrin foam had degenerated or had been adsorbed to some extent and remained as irregular, friable fragments. The spinal root of the first sacral was freely movable and not adherent to adjacent structures. The sciatica subsided after decompression of the first sacral root on the left.

The control of this relatively uncomplicated type of hemorrhage justifies a brief description of fibrin foam for those who are unfamiliar with its characteristics and usage. Fibrin foam is prepared from human fibrinogen and human thrombin and in the dry state appears dull white, dry and brittle. A fairly large mass of fibrin foam is packaged sterile in a dry state with a vial of dried human thrombin. A third vial contains 30 cc. of sterile isotonic solution of sodium chloride. At the operating table the thrombin is dissolved in the saline solution by means of vigorous stirring. Rather large fragments of fibrin foam are dropped into the thrombin solution. Further stirring will cause fragmentation of the fibrin foam into pieces too small for practical use. Fragments of the foam may then be cut or formed as the technical situation demands. As prepared at present the amount is sufficient for craniotomy. It may be used economically for successive disk or nerve cases by removal of a single fragment of foam prior to operation and by aspiration of sufficient thrombin solution to penetrate the fibrin matrix of this fragment.

The use of fibrin foam for the control of venous hemorrhage incidental to removal of a herniated nucleus pulposus appears to be a distinct contribution to more refined disk surgery. Such hemorrhage may be controlled by pressure of a warm saline pledget of cotton or by a muscle stamp. It is vastly simplified by the use of fibrin foam. From the single observation made twenty-one days after hemilaminectomy, it likewise appears that fibrin foam may prevent adherence of the nerve root to adjacent tissues and may prevent as well scar tissue formation from a resolving post-operative hematoma in the region of the laminal interspace. Both sequelae of disk surgery may account for residual or recurrent postoperative sciatic pain.

CASE 2.—Mortar shell injury to peroneal and tibial nerves. Neurolysis. Neurorrhaphy.

C. G. H., 2d lieutenant, aged 31, received multiple wounds from mortar shell fragments on Jan. 21, 1944, including one in the right popliteal space. Neurologic examination suggested a complete section of the common peroneal nerve and an incomplete lesion of the tibial nerve. On April 17 the injured area was explored. An end to end tantalum wire suture of the common peroneal nerve and a neurolysis of the tibial nerve were performed. Regeneration has proceeded at a normal rate since operation.

The methods for the control of hemorrhage from the involved peripheral nerves in this case by the use of fibrin foam were identical with those followed in the

remaining cases of this series. It is not an uncommon accident during neurolysis or transposition of a peripheral nerve to divide a longitudinal or entering epineural artery or vein. Such hemorrhage closely adjacent to living axons cannot be controlled by the application of a silver clip or by the use of the electrocautery. The application of a 3 to 4 millimeter fragment of fibrin foam, followed by pressure exerted on a moist cotton patty, controls such hemorrhage completely and should not be followed by tissue reaction seen after the use of a muscle stamp. The fibrin foam mass should be left in place. Excessive hemorrhage from nerve ends transected for nerve suture or nerve grafting may militate against the success of the intended procedure. The patient, successive application of foam fragments with firm pressure conducted through moist cotton pledgets will eventually control this troublesome hemorrhage. No resultant edema or other changes in the structure of the nerve ends have been observed. No opportunity has developed to study foam fragments at secondary operation in such injuries.

CASE 3.—Resection of cerebral cicatrix. Tantalum plating of skull defect.

A. J. L., 2d lieutenant, aged 25, sustained a mortar shell injury of the right parietal region of the skull on Dec. 23, 1943 with involvement of scalp, skull, dura and cerebral tissue. Débridement was done within ten hours of the injury and the convalescence was uneventful. On admission to the Walter Reed General Hospital on March 25, 1944 he showed a residual and rapidly clearing left hemiplegia and an oval pulsating defect in the right parietal area. Electroencephalography revealed high voltage 2 to 3 second waves with slow wave, out of phase focus over the site of injury. On May 10 a shallow cortical scar was resected and the skull defect repaired with tantalum. Postoperative study of electrical activity of the cortex showed much improvement with abnormal waves appearing only with hyperventilation.

In this instance the area of cortical resection was filled with broad, thin sheets of fibrin foam, approximately 2 to 5 mm. thick, with prompt cessation of hemorrhage. This procedure has been followed in other scar resections with equal success. In all cases requiring skull defect repair the extradural bleeding that may follow revision of the dura has been controlled by small fragments placed between dura and bone, insuring complete hemostasis beneath the plate.

CASE 4.—Resection of occipital lobe and glioblastoma.

W. L. B., private, aged 23, a Negro, developed headache, vomiting, diminished visual acuity and mental confusion over a period of three months. On admission, neurologic examination noted irrationality and confusion with cervical rigidity, minimal papilledema and no localizing signs of import. Ventriculography disclosed a cyst with ragged, irregular contours in the right occipital lobe. On May 12, 1944 the right occipital lobe was resected through the confluence of the body and posterior horn of the lateral ventricle. During this procedure a large posterior cerebral vein tore away from the longitudinal sinus. The ensuing venous hemorrhage was promptly and permanently controlled by a thick stamp of fibrin foam, held in place by firm pressure over a moist cotton strip. Convalescence from craniotomy was uneventful.

In eight more or less similar cerebral resections for tumor, either oozing from cerebral tissue or massive arterial and venous hemorrhage from tumor bed or sinus apertures have been controlled effectively. A striking example of the effectiveness of this hemostatic agent is afforded by a perusal of the following case:

CASE 5.—Complete removal of acoustic neuroma, right.

S. K.; T/3, aged 26, was operated on in an overseas theater for cerebellar tumor. The procedure was terminated prematurely because of excessive hemorrhage from the right lateral recess. The neurologic findings were typical of a cerebello-pontine angle tumor on the right. On April 20, 1944 a right acoustic neuroma was resected completely. Diffuse, moderately severe hemorrhage from poorly visualized vessels lying along the lateral and anterior borders of the pons was controlled readily by the application of narrow strips of fibrin foam. On April 28 the craniotomy wound was reexplored because of hyperpyrexia and increased intracranial pressure. The lateral recess was clear and the fibrin foam could be seen as an irregular, reddish brown, granular mass without significant tissue reaction. The operative area was sterile. Following spinofacial anastomosis the patient was sent on a therapeutic furlough.

CASE 6.—Bifrontal, compound, depressed skull fracture with cerebral laceration.

B. L., corporal, aged 24, was engaged in welding a 50 gallon steel drum when an explosion of unknown origin occurred. A fragment of steel penetrated above the nasion; its removal was followed by drainage of brain tissue and cerebrospinal fluid from the laceration and from the nose. A débridement was carried out twenty-four hours after the injury through a transverse, midfrontal laceration 9 cm. long. The medial and inferior surfaces of both frontal lobes were extensively lacerated. After electrocanterization of moderate sized arteries and veins, diffuse hemorrhage persisted in spite of warm saline cotton packs. This bleeding was controlled instantly by the application of thin, round disks of fibrin foam. Bilateral dural grafts were sutured in place and the soldier has returned to duty.

This experience, although an isolated one, justifies a thorough clinical trial of this hemostatic agent in the field of acute cerebral injuries.

SUMMARY

Fibrin foam has been used as a hemostatic agent in 226 neurosurgical operations completed in an Army Neurosurgical Center. The technical procedures have consisted of peripheral nerve neurolysis, neurorrhaphy and nerve graft, excision of cerebral scar with tantalum plating of skull defects, hemilaminectomy for rupture of an intervertebral disk, craniotomy for tumor, laminectomy and débridement for acute cerebral injury. In each instance the desired hemostatic effect has been secured promptly and has contributed in large measure to the execution of the particular operation. No clinical untoward reactions that could have been attributed to the use of fibrin foam have been observed. There were but two opportunities to observe a possible tissue reaction to fibrin foam, and these negative observations were consistent with those previously reported. The application of this method of hemostasis to war injuries of the brain seems most promising.

Hypochondriasis.—Hypochondriasis may be found as a mental habit in a fairly large group of individuals of medium intelligence who have led narrow lives without many interests and who have been prone to accept the statements found in newspapers relative to medicine and advertisements in good faith. They are prone to interpret mild physical discomforts due to fatigue, position or unhygienic living as symptoms of serious physical illness and to react accordingly. It is often most difficult to change their delusions about themselves. They will not even accept the reassurances of the family doctor that they do not show any symptoms of the disease of which they complain, as he cannot tell how they feel. They know they have heart disease because they are so short of breath when they go upstairs, etc.—Davis, John E.: *Principles and Practice of Rehabilitation*. New York, A. S. Barnes & Co., Inc., 1943.

THE MALE CLIMACTERIC. ITS SYMPTOMATOLOGY, DIAGNOSIS AND TREATMENT

USE OF URINARY GONADOTROPINS. THERAPEUTIC TEST WITH TESTOSTERONE PROPIONATE AND TESTICULAR BIOPSIES IN DELINEATING THE MALE CLIMACTERIC FROM PSYCHONEUROSIS AND PSYCHOGENIC IMPOTENCE

CARL G. HELLER, M.D., PH.D.

VANCOUVER, WASH.

AND

GORDON B. MYERS, M.D.

DETROIT

During the past few years several articles¹ have been published in medical journals about a syndrome occurring in middle aged men which has been termed the male climacteric. The syndrome has been characterized principally by nervousness, psychic depression, impaired memory, the inability to concentrate, easy fatigability, insomnia, hot flashes, periodic sweating and loss of sexual vigor. The chief basis for the diagnosis of male climacteric in published reports has been the similarity of the symptoms to those of the female menopause and the relief sometimes afforded by androgenic therapy. The claim has been made² that most men and all women pass through the climacteric during the fifth decade and that the diagnosis of male climacteric is frequently missed. Quite recently this concept has been popularized by Paul de Kruif in the July 1944 issue of *Reader's Digest*, and physicians are deluged with requests for treatment by hopeful readers.

No objective evidence has been brought forward to prove that the male climacteric is an actual clinical entity or to differentiate it conclusively from psychoneurosis or psychogenic impotence. In fact, ordinary clinical experience arouses considerable skepticism as to the existence of the male climacteric because of (a) the similarity between symptoms attributed to this syndrome and those referable to psychoneurosis, (b) the retention of fertility by most men well into old age, (c) the absence of regressive changes in secondary sexual characteristics of most elderly men comparable to those which customarily occur in women after the menopause. In most elderly women there are unmistakable signs of ovarian failure, namely atrophy of the uterus, vagina, external genitalia and breasts, a deepening of the voice, a tendency toward hirsutism and a loss of femi-

nine bodily contours. In contrast, most elderly men exhibit no physical signs of testicular failure: genitalia and secondary sexual characteristics show no regressive changes, beard and bodily hair remain intact, and bodily contours remain masculine. Skepticism toward the existence of the male climacteric is clearly expressed in a recent editorial in *THE JOURNAL*.³

Our purpose in this communication is to present evidence which will provide answers to the following questions: 1. Is there an organic basis for justifying the claim that the male climacteric is a true clinical entity? 2. Is it possible to distinguish between the male climacteric and psychoneurosis or psychogenic impotence either clinically, by laboratory methods or both? 3. If the syndrome exists, what therapy is advisable? 4. Is the male climacteric a normal accompaniment of the aging process or is it a pathologic problem?

To answer the foregoing questions we needed some objective criterion of testicular function. It seemed likely that the titer of urinary gonadotropins might reflect gonadal function in the male as well as in the female.

An elevation in the titer of gonadotropins excreted in the urine has proved to be an accurate index of ovarian failure. This invariably accompanies the naturally occurring female menopause⁴ and follows bilateral oophorectomy within one to four weeks.⁵ The elevated titers of urinary gonadotropins persist for the remainder of the patient's life.⁴ There is considerable evidence to suggest that the abnormally great excretion of gonadotropins is due to failure of utilization of this hormone by the nonfunctioning ovaries.⁶ Therefore it was decided to perform gonadotropic assays in the male.

Before gonadotropic assays could be used for the differentiation between the male climacteric and psychoneurosis, it was necessary to determine whether elevations truly reflected testicular insufficiency. Therefore determinations were made in a series of normal controls ranging from 22 to 98 years of age and in a group of men with known failure of testicular function. The assays were performed in an identical manner on patients complaining of symptoms claimed to be associated with the male climacteric. In addition, microscopic examination of testicular biopsy specimens was made in some of the cases.

METHODS

Urinary gonadotropic excretion was determined on specimens collected during a twelve hour overnight period. These were concentrated by precipitating the protein gonadotropins with 95 per cent ethyl alcohol, subsequently dialysing off toxic substances and reprecipitating with 95 per cent ethyl alcohol. The final precipitate evolving from this procedure was dissolved in 6 cc. of tap water and injected into an immature (22-24 day old) female albino rat in 1 cc. portions twice

daily for three days.⁷ The amount of the gonadotropic hormone in the concentrate was determined biologically from the increase in weight of ovaries and uterus at autopsy performed sixteen to twenty-four hours after the last injection was made. It was found expedient to express gonadotropic activity in terms of actual ovarian weights elicited by the concentrate of each twelve hour specimen. Normal ovarian weights for the strain of rats used ranged from 8 to 16.2 mg. and averaged 12 mg.

Histologic technics used on the biopsy specimens of the testes were routine hematoxylin and eosin stains, Masson's trichrome stain and Giemsa's stain.

RESULTS IN MEN WHOSE TESTICULAR FUNCTION
HAD BEEN DEFINITELY ESTABLISHED

Urinary gonadotropic titers of 25 normal men are contrasted with those of 12 surgical castrates and 8 functional prepuberal castrates in chart 1 and table 1.

Normal Men.—Among the normals, all decades were represented from the third through the tenth. All the normal men gave histories of normal sexual function and none had symptoms suggestive of the climacteric. The presence of normal testes was confirmed by biopsy in 10 men, 7 of whom were in the sixth decade or beyond. The 17-ketosteroid excretion was considered normal in 12 cases in which this assay was performed. None of the normals excreted sufficient gonadotropins to cause detectable stimulation of the ovaries of the assay rats. This was evident by the fact that the average ovarian weight after injection with concentrates of the urine of the normal men was only 12.3 mg.,⁸ which is similar to the ovarian weights in uninjected control rats.

Castrated Men.—In contrast, all 12 castrates excreted large amounts of gonadotropins, as shown by the fact that urinary concentrates caused a fivefold increase in

as compared with 12.3 mg. for rats injected with concentrates of urine from normal males. The striking increase in ovarian weight was due partly to follicular maturation and partly to corpus luteum formation. This indicated that the urine of castrate men contained excessive quantities of either of two separate gonado-

TABLE 1.—Gonadotropic Hormone Titters in Cases of Known and Unknown Testicular Function

	Clinical Category	No. of Cases	No. of Assays	Ovarian Weight, Mg.
Normal controls	Normal males.....	25	47	12.3
Controls consisting of cases of proved testicular failure	Castrated males.....	12	30	62.6
	Functional prepuberal castrates *.....	8	36	86
	Seminiferous tubule failure *.....	20	74	80.7
Experimental groups	Psychoneurotic males.....	15	25	13.3
	Male climacterics.....	23	100	62.8

* All these subjects were proved to have testicular failure by microscopic examination of a testicular biopsy specimen taken in each instance.

tropic hormones, one capable of stimulating the growth of ovarian follicles in the female or seminiferous tubules in the male (follicle stimulating hormone), the other capable of producing luteinization in the female or of stimulating the interstitial cells of the male (luteinizing hormone).

Further evidence for the direct correlation between gonadotropic titers and testicular function was obtained in 6 patients on whom gonadotropic assays were performed before castration and one month or more after castration. The preoperative titers were normal, the average ovarian weight of assay rats being 12 mg. This was interpreted as indicating normal testicular function. Microscopic examination of the ablated testes showed them to have normal structure, which confirmed the impression that these men had normal testicular function preoperatively. The gonadotropic titers after castration were high, the average ovarian weight of assay rats being 58 mg. The elevation of gonadotropins is probably due to failure of utilization by the ablated testes, which normally metabolize this hormone. Therefore the rise of gonadotropins is interpreted as a reflection of testicular failure.

Functional Prepuberal Castration in Men.—Elevated gonadotropins were also observed in cases of spontaneous prepuberal destruction of the testes. This was seen in 8 cases in which operation revealed either the absence or the complete atrophy of the testes associated with wolffian duct derivatives in the scrotum⁹ (chart 1 and table 1).

Hyalinization of Seminiferous Tubules and Clumping of Leydig Cells.—From a third type of primary failure of the testes we obtained additional corroboration of the fact that when the testis fails, in the absence of pituitary disease, there is always a compensatory rise in urinary gonadotropins. In this syndrome, only recently described by Klinefelter, Reifenstein and Albright¹⁰

Chart 1.—Urinary gonadotropic titers.

the weight of the ovaries of the assay rats (table 1). The average ovarian weight of rats injected with concentrates of urine from castrate males was 62.6 mg.,

7. Heller, C. G., and Chandler, R. E. Gonadotropic Hormone Modification of the Alcohol Precipitation Assay Method, *J. Clin. Endocrinol.* 2: 252-253 (April) 1942. Heller, C. G.; Lawson, H., and Seyringhaus, E. L. The Immature Rat Uterus as an Assay End Point for Gonadotropic Substances, *Am. J. Physiol.* 121: 364-378 (Feb.) 1938.
8. The titers for the normal males in this series compare favorably with the low titers established for normal males by Heller, E. J.; Heller, C. G., and Seyringhaus, E. L.: Gonadotropic Hormones: Assays of Human Male Urine, *Endocrinology* 29: 1-7 (July) 1941.

9. Heller, C. G.; Nelson, W. O., and Roth, A. A.: Functional Prepuberal Castration in Males, *J. Clin. Endocrinol.* 2: 573-588 (Nov.) 1943.

10. Klinefelter, H. F., Jr.; Reifenstein, E. C., Jr., and Albright, F. Syndrome Characterized by Gynecomastia, Aspermatogenesis Without A-Leydigism and Increased Excretion of Follicle Stimulating Hormone, *J. Clin. Endocrinol.* 2: 615-627 (Nov.) 1942.

and by Heller and Nelson,¹¹ a definite correlation has been established between the hyalinization of the seminiferous tubules, Leydig cell failure and elevated gonadotropins. The elevation of gonadotropins can be seen for 20 of our cases in table 1.

Thus, in every proved case of primary gonadal failure, impaired or absent gonadal function was accompanied by a rise in urinary gonadotropic excretion. The high concentrations of gonadotropins in the urine were in striking contrast to the low titers encountered in normal men of the same age. Therefore it was felt the gonadotropic titer could be safely utilized as a measure of gonadal failure in cases showing symptoms suggestive of the male climacteric.

RESULTS IN MEN WHOSE TESTICULAR FUNCTION WAS UNDER INVESTIGATION

Urinary gonadotropic assays were performed on a series of 38 men, all of whom complained of constitutional and psychic symptoms more or less resembling those of the female menopause. In addition, 32 of the 38 patients complained of impotence. On the basis of the results of the assays, the cases could be sharply

Chart 2.—Gonadotropic assays.

subdivided into two groups, designated temporarily as groups A and B.

A. Normal gonadotropic assays were obtained in 15 of the 38 patients. The average assay ovarian weight was 13.3 mg. for this group of 15 and compared very closely with the figure of 12.3 mg., which was the average assay ovarian weight for the 25 normal males. The striking uniformity of individual cases in the two groups is evident from a comparison of charts 1 and 2. From the fact that the gonadotropic titers of the cases in group A corresponded with those of normal males it was concluded that testicular failure had not occurred.

B. High gonadotropic assays were obtained in 23 of the 38 patients. The titer of each of the 23 cases was unequivocally higher than any titer obtained in the 15 cases in group A or any titer in the 25 normal control cases, as is evident from studying charts 1 and 2. The amount of gonadotropic hormone excreted in these 23 cases corresponded closely to that excreted by the castrated controls. The average assay ovarian weight of the 23 cases in group B was 52.8 mg. as compared with 62.6 mg. for the castrated controls and contrasted

with 12.3 mg. and 13.3 mg. for the normal controls and the 15 cases in group A, respectively. It was concluded that these 23 men in group B had testicular failure.

Testicular biopsies were performed in 8 of the 23 cases in group B as a check on the reliability of gonadotropic assays in predicting testicular failure. Histologic evidence corroborating the presence of testicular failure was obtained in all 8 cases. In 5 instances the biopsies revealed reduction in size and in activity of the seminiferous tubules and reduction in the size and number of Leydig cells. The latter were abnormal in granulation and lipid content. In 3 cases the biopsy findings simulated those of Klinefelter's syndrome¹² and are described in detail by Nelson.¹²

Therapeutic test was applied in 29 cases, including 9 from group A and 20 from group B. The therapeutic test consisted in an evaluation of the clinical response to testosterone propionate¹³ given intramuscularly in doses of 25 mg. five times weekly for two to four weeks.

Results of the Therapeutic Test in the Patients with High Gonadotropins (Group B).—Definite improvement in the symptomatology was noted by the end of the second week in all of the 20 cases treated. Complete abolition of all vasomotor, psychic, constitutional and urinary symptoms (table 2) was accomplished by the end of the third week in 17 of the 20 cases treated. In the remaining 3 cases vasomotor and urinary symptoms were abolished but the psychic and constitutional symptoms persisted despite continuation of treatment for several months and doubling the dosage for brief periods. It was concluded that these three persons were suffering from involutional melancholia. Sexual potency was restored to normal with these doses in all but 2 cases, in 1 of which involutional melancholia was present. With an increase in dosage of testosterone propionate to 50 mg. five times weekly, sexual vigor in both previously refractory cases exceeded that of normal men.

In 14 cases therapy was subsequently withheld for from four to fifteen weeks and in all instances the symptoms returned and sexual potency was again lost. On resumption of the therapy with testosterone propionate, relief from symptoms was again afforded and sexual potency returned. Thus the specificity of therapy was established. To investigate further the possibility that the improvement might have been due to suggestion, placebo injections were administered. Ampules containing 1 cc. of sesame oil, packaged similarly to the original testosterone propionate, were substituted without the patient's knowledge in several cases. No improvement was noted in any case.

In chart 3 a case is presented to illustrate the abolition of symptoms and restoration of potentia by testosterone propionate, the recurrence of symptoms and loss of potency after discontinuance of therapy, the failure of sesame oil placebo and the subsequent control by resumption of androgenic therapy. The results of the therapeutic test provide confirmatory evidence that the symptoms and loss of potentia in the group with elevated gonadotropins (group B) were due to testicular failure.

Results of the Therapeutic Test in the Patients with Normal Gonadotropins (Group A).—Of the 9 men subjected to the therapeutic test 7 had loss of sexual

potency and 8 had some of the other symptoms listed in table 2. In 3 instances there was evanescent improvement in symptomatology noted during the first week of therapy. However, by the end of the second to fourth weeks none of the 9 patients demonstrated any improvement whatever in either the general symptomatology or the sexual vigor.

The results of the therapeutic test in the group with normal gonadotropins (group A) provide confirmatory evidence that loss of potentia and symptoms in these patients were not due to testicular failure. This conclusion was corroborated by the fact that normal men experience little, if any, increase in sexual potency or in well being by taking the male sex hormone.

Symptomatology.—By the foregoing objective tests the 38 cases could be sharply separated into two groups: A, consisting of 15 patients having normal testicular function as evidenced by normal gonadotropic excretion and failure to respond to the therapeutic test; B, consisting of 23 patients having testicular failure as evidenced by high gonadotropin output, comparable to castrates, histologic evidence of testicular degeneration and specific response to the therapeutic test.

Chart 3.—Therapeutic test.

Symptoms Encountered in the Group with Testicular Failure.—After the symptoms of the group with elevated gonadotropins were analyzed it was evident that they fell into five categories: (1) vasomotor, (2) psychic, (3) constitutional, (4) urinary and (5) sexual. The various symptoms classified in this manner are listed in table 2.

The urinary frequency and hesitancy and decrease in size and force of the stream are undoubtedly related to enlargement of the prostate and decreased bladder tonus which accompany testicular failure. The urinary symptoms are relieved by testosterone, in all probability, because of improvement of bladder tonus, not because of any direct effect on the prostate.

The vasomotor, psychic and constitutional symptoms are identical with those encountered in the female menopause. Of course, no patient exhibited all of the symptoms listed. The most constant symptom was the loss of sexual potency, which was a complaint of all 23 patients. This was usually but not invariably accompanied by loss of libido. Psychic and constitutional symptoms, particularly nervousness and fatigability, were also invariably present. A somewhat less frequent but more characteristic symptom was hot flashes identical with those described by menopausal women. A significant feature from a diagnostic standpoint was

the tendency for loss of sexual potency, hot flashes and nervousness to make their appearance concurrently. While the onset was never fulminant, the patient could usually tell the month or season the symptoms began. The etiologic relationship between the symptoms in table 2 and the testicular failure was borne out by the specific relief afforded by androgens, the recurrence after cessation of androgenic therapy and unresponsiveness to placebos.

Symptoms Encountered in the Group with Normal Testicular Function.—The majority of the men in group A also complained of loss of potency usually accompanied by psychic and constitutional symptoms resembling those of group B and occasionally by vasomotor and urinary symptoms listed in table 2. A notable

TABLE 2.—Symptoms According to Categories

1. Vasomotor:	hot flashes chilliness sweating palpitation increased pulse rate headache
2. Psychic:	nervousness irritability insomnia depression self depreciation antisocial tendencies crying spells suicidal tendencies paresthesias pruritus inability to concentrate
3. Constitutional:	weakness fatigue muscle pains muscle cramps arthralgia anorexia nausea and vomiting abdominal pain constipation weight loss
4. Urinary:	decreased force decreased size frequency hesitancy
5. Sexual:	diminution of libido decreased erections

difference was the rarity of true hot flashes in group A. Often the symptoms had been present for most of the patient's adult life or occasionally had been very abrupt in onset, coincident with some psychic trauma.

COMMENT

At the conception of this investigation four questions were postulated. On the basis of the data presented, an attempt will now be made to answer each question.

1. *Is there an organic basis for justifying the claim that the male climacteric is a true clinical entity?* This is answered in the affirmative by the finding of testicular failure in 23 of the patients studied. The objective evidence for the testicular failure consisted of (a) elevation in gonadotropic excretion, comparable quantitatively with that occurring in castrated males and men with primary gonadal failure; (b) histologic signs of testicular atrophy or degeneration in all eight cases subjected to testicular biopsy. The etiologic relationship between the demonstrated testicular failure and the

clinical picture was borne out by (a) the resemblance of the symptoms of this group of cases to that of the definitely established pattern of the female menopause, with the addition of occasional urinary symptoms and the invariable association of decrease in sexual potency; (b) the specific restoration of potency and alleviation of the menopausal-like symptoms by applying the therapeutic test of substitution therapy with androgens; (c) the reappearance of symptoms after withdrawal of androgens, and (d) the complete failure of placebos.

It was therefore concluded that these 23 patients were true examples of the male climacteric!

2. *Is it possible to distinguish between the male climacteric and psychoneurosis and psychogenic impotence, either clinically or by laboratory methods?* Presumptive differentiation may be made by a careful history combined with a therapeutic test. For a positive differentiation, however, laboratory tests are necessary. The assay of urinary gonadotropins provided a sharp distinction between known normal and known castrated men and an equally clearcut distinction between group A and the male climacterics (group B). By this means it was established that the climacteric patients had testicular failure and that group A did not.

This was further supported by the failure of the patients in group A to respond to the therapeutic test. It was therefore concluded that the symptoms of the patients in group A were not due to testicular failure and that the probable basis for the symptoms was psychoneurosis or psychogenic impotence!

On the basis of clinical symptomatology alone, a tentative but not an absolute differentiation can be made. The most important diagnostic points are: 1. Character of the symptoms: The symptom complex of the male climacteric corresponded much more closely to the female menopause than did the symptom complex of the average psychoneurotic. Typical hot flashes, identical with those occurring in the female menopause, are strongly suggestive of the male climacteric but occasionally may occur in psychoneurosis. On the other hand, the absence of hot flashes by no means excludes the diagnosis of the male climacteric. In fact, this symptom was absent in about 40 per cent of our cases. 2. The mode of onset: The diagnosis of male climacteric is strongly suggested when a past history is obtained of normal sexual function up until a definite month or season, at which time loss of potentia, hot flashes and nervousness appear simultaneously. A diagnosis of psychoneurosis is suggested when the symptoms have been present throughout adult life or are abruptly precipitated by psychic trauma. Often a careful history will uncover the emotional factors responsible for the impotence and symptoms of the neurotic. 3. The therapeutic test will aid in separating the two groups, since the climacterics can be expected to make a striking improvement, whereas the psychoneurotic usually do not show a specific response.

As the study progressed and the differences in the clinical pattern between the climacteric and the psychoneurotic became evident, a large number of the psychoneurotic were eliminated on a clinical basis. This accounts for the fact that 23 of the 38 patients in the series proved to be examples of the male climacteric and that only 15 psychoneurotic patients were investigated by laboratory methods.

3. *What therapy is advisable?* Before instituting treatment it is necessary to establish the diagnosis of the male climacteric and to exclude the following contraindications to androgens: (1) the presence or suspicion of carcinoma of the prostate in particular and any carcinoma in general, since the steroids have a carcinogenic action; (2) the presence of edema, since testosterone tends to produce sodium, and hence water, retention; (3) any case showing normal testicular function, since testosterone will inhibit spermatogenesis in normal males and may, in addition, cause disuse atrophy of the normal Leydig cells. In this connection we have followed the gonadotropic excretion in a normal man given a long course of testosterone propionate therapy and found that after discontinuance of the androgen the gonadotropins rose to levels corresponding to those following castration. Whether these changes are permanent or not is still uncertain, but it is entirely possible that ill advised treatment with testosterone may cause permanent sterility.

Therapeutic Test Suggested for Establishing the Diagnosis of Male Climacteric.—In clinical practice laboratory procedures that will positively differentiate climacteric from psychoneurotic patients may not be available. Although the testicular biopsy is a simple surgical procedure, it may not always be feasible. Under such circumstances it may be necessary to resort to the following therapeutic test: Administer 25 mg. of testosterone propionate by intramuscular injection five days weekly for a period of two weeks. Evaluate the clinical status at that time, noting the effect on symptoms and sexual potency. If, at the end of the two week trial of therapy, the patient has shown no improvement, either of two conclusions may be justifiable: (1) The patient does not have the male climacteric or (2) he will need such an excessively large daily dosage of testosterone that treatment is financially impractical. If the patient does respond it may be necessary to determine whether the improvement is actually due to specific relief of testicular failure or whether it is merely due to suggestion. Withdrawal of therapy until symptoms return and then reinstitution of therapy with placebos may be required to settle the question.

If the diagnosis of the climacteric is positively established by these procedures and the response to the therapeutic test is satisfactory, the minimal dosage for control can next be determined by trial and error. In cases of complete testicular failure, satisfactory control will usually be obtained by administering 25 mg. of testosterone propionate three times weekly. In some cases injection of 25 mg. once a week will suffice. Rarely 10 mg. once or twice weekly may maintain a patient satisfactorily.

In our experience with cases in which a diagnosis of testicular failure has been clearly established, eunuchoids as well as climacteric patients, the use of methyl testosterone has been disappointing both by the oral and by the sublingual routes. The recommended oral dose of four to six times the injection dose was inadequate for satisfactory maintenance. Larger doses often caused nausea and vomiting and were too expensive to be practical. The sublingual use of methyl testosterone, either in solution or in tablet form, is not recommended because it has either been ineffective or

has produced undesirable reactions such as burning of the mouth, swelling of the gums, nausea, vomiting, heartburn, weakness of the legs, tinnitus, vertigo and headache.

If more than two intramuscular injections of testosterone propionate are necessary per week for maintenance effects, it is suggested that pellets of free testosterone be implanted subcutaneously in the thighs through a pellet injector. The implantation of 4 to 8 pellets weighing 75 mg. each will provide excellent control for periods of six to ten months.

4. *Can the average male expect to experience the male climacteric?* We believe not. Our conviction comes from observations of gonadotropic excretion in normal males, examination of testicular tissue removed at orchiectomy for carcinoma of the prostate in aged men, the sexual history of elderly normal men and the bodily configuration and physical examination of elderly men. All indicate that both the germinal and the hormonal function of the testes is preserved well into senility in the average man. Reduction of function is admitted, but fairly adequate maintenance occurs in most cases studied. In addition, it should be noted from chart 2 that the male climacteric is not confined to middle and old age but may occur as early as the third decade. The youngest patient in this series of male climacterics was 25 years of age.

Thus we conclude that, whereas in the female the menopause is an invariable and physiologic accompaniment of the aging process, in the male the climacteric is an infrequent and pathologic accompaniment of the aging process.

The demonstration that testicular failure is responsible for the male climacteric, a syndrome whose clinical manifestations are entirely subjective and easily confused with psychoneurosis, establishes an organic basis and physiologic treatment for a small segment of the large field encompassed by the term psychoneurosis.

SUMMARY

The diagnosis of the male climacteric was established in 23 cases by the finding of pronounced elevation in gonadotropic hormone excretion, comparable quantitatively to that occurring in castrates. This was corroborated in all 8 cases subjected to biopsy by histologic evidence of testicular atrophy and degeneration. The diagnosis was further supported in all 20 cases treated by specific response to a therapeutic test with androgens.

A clearcut differentiation of the male climacteric from psychogenic impotence was made by urine gonadotropic assays, which were decidedly elevated in the former group and normal in the latter. A simple therapeutic test is helpful in distinguishing between these two conditions.

The symptomatology of the male climacteric is different from that of psychoneurosis and psychogenic impotence. Satisfactory therapeutic results were obtained by intramuscular injections of testosterone propionate and by implantation of testosterone pellets but not by the oral or sublingual administration of methyl testosterone.

Although the male climacteric may occur as early as the third decade, it is a relatively rare syndrome, probably affecting only a small proportion of men who live into old age.

RECURRENCE RATES IN RHEUMATIC FEVER

THE EVALUATION OF ETIOLOGIC CONCEPTS AND CONSEQUENT PREVENTIVE THERAPY

MAY G. WILSON, M.D.

AND

ROSE LUBSCHEZ

NEW YORK

The clinical course of rheumatic fever is characterized by frequent recurrence of manifestations of the disease and a varying number of intercurrent years of freedom from symptoms. The average risk for a recurrence of rheumatic fever has never been defined. Current etiologic concepts and consequent preventive therapy are based in large measure on a comparison of the number of recurrences of rheumatic fever among experimental and control groups of rheumatic patients.

The majority of reported studies have been made on small groups of patients. It is rarely possible for any one investigator to assemble a representative series of sufficient size for adequate analysis. Conclusions are frequently drawn from the summated observations of several small but apparently comparable studies.

The pooling of experience is an acceptable practice, provided each study which is included represents a random selection in which experimental and control subjects have been selected alternately. This is essential in order to minimize the possibility of chance being responsible for any observed difference in the two groups. In addition, diagnostic criteria and observations must be uniform, environmental conditions and age constitution comparable. The published studies which have been summated in rheumatic fever do not appear to meet these basic requirements.¹

To obtain a measure of the expected risk of overt recurrence of rheumatic fever, a series of 549 records of a representative group of rheumatic patients was selected for analysis. These patients were under continuous uniform medical supervision in the cardiac clinic.²

METHOD OF ANALYSIS

The usual procedure for constructing a life table was followed, using one person-year of life experience as the unit for study.³ To obtain the rate of recurrence,

These studies were assisted by a grant from the Commonwealth Fund. From the New York Hospital and the Department of Pediatrics, Cornell University Medical College.

Dr. Lowell J. Reed has shown continued interest and given constructive criticism during the progress of these studies.

Read in a symposium on "Rheumatic Fever" before the Section on Pediatrics at the Ninety Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

1. Thomas, C. B. The Prophylactic Treatment of Rheumatic Fever by Sulfanilamide, *Bull. New York Acad. Med.* 18: 509, 1942. Paul³

2. Only the records of patients whose onset and course of disease were accurately documented were included. In 50 patients the only recurrent attacks were growing and joint pains. These were not included in this presentation. Of the remaining 499 patients, 256 experienced one or more attacks of arthritis or chorea, alone or combined, and in 243 active carditis with or without chorea and arthritis characterized the course. The duration of disease for the age group 4 to 16 years averaged eight years. Within this period, 10 per cent died. In 46.9 per cent mitral insufficiency, in 38.4 per cent mitral insufficiency and stenosis and in 14.8 per cent mitral and aortic lesions were present. Additional analyses were made for those 345 patients reaching the ages of 17 to 25 years for whom the average duration was an additional six years, and 108 records of rheumatic families including 182 rheumatic individuals were included for the analysis of the influence of environment (Wilson, May G.: *Rheumatic Fever*, New York, Commonwealth Fund, 1940, pp. 225-375).

3. Frost, W. H.: *Papers of Wade Hampton Frost, A Contribution to Epidemiological Method*, edited by K. F. Maczey, New York, Commonwealth Fund, 1941, p. 586.

the ratio of the number of recurrences to the person-years of life experience at each age from 4 to 25 years was calculated. For 499 patients experiencing a major recurrence (arthritis, chorea and active carditis, alone or combined), age specific rates for different patterns and degrees of severity of the disease were made. In

Chart 1—Age specific recurrence rates for 499 rheumatic individuals comprising 5,677 person years

addition, comparison of the recurrence rates in twelve consecutive calendar years from 1924 to 1935 and the rate of recurrence for patients living under relatively favorable and unfavorable environmental conditions were determined.

OBSERVATIONS

Among 499 patients between the ages of 4 and 16 years, representing 3,957.0 person years of life experience, 31 per cent did not have a recurrent major attack. There were 817 recurrent manifestations of arthritis, chorea and active carditis, alone or combined. Among 345 of these patients who reached the ages of 17 to 25 years, representing 1,720.0 person years of life experience, there were 64 major recurrent attacks. Eighty-seven per cent did not have a major recurrence.

AGE SPECIFIC RATES OF RECURRENCE DURING 5,677 PERSON YEARS OF LIFE EXPERIENCE

In table 1 and chart 1 it may be noted that the age specific recurrence rates reflect the natural history of the disease. The rates are highest between the ages of 4 and 13 years, having a peak incidence at about the age of 7 years. After the age of 13 years there is a significant downward trend, which reaches its lowest sustained level after the age of 17 years. The average recurrence rate from 4 to 13 years is 25.0 per cent, from 14 to 16 years the average rate drops to 8.7 per cent and from 17 to 25 years the average recurrence rate is 3.7 per cent. For a random sample between the ages of 4 and 16 years the average risk of recurrence is 20.6 per cent.

The variation in the risk of recurrence at different ages must be considered in selecting patients for study. It is obvious that the age constitution must be com-

Chart 2—The risk of recurrence in relation to the last rheumatic attack

parable in control and experimental groups. In a small series the presence of only a few patients of a different age in one of the groups might well account for any difference observed.

The interval of time elapsing between recurrent attacks for patients between the ages of 4 and 16 years

was also found to be an important influential factor in the risk of future recurrence. The risk of recurrence during the year immediately following a major episode is 38.7 per cent compared to 11.2 per cent in the year immediately following one year of freedom from recurrence. The average rate of recurrence within one year or more after a major rheumatic episode was twice as great as that following at least one year of freedom and three times as great as that following at least two years of freedom from symptoms, 20.6 per cent, 10.7 per cent and 6.6 per cent, respectively (chart 2 and table 2).

It is generally believed that the incidence of rheumatic fever varies in different years. Analysis of the rate of recurrence in twelve consecutive calendar years from 1924 to 1935 did not reveal any significant difference which could be attributed to epidemiologic factors

TABLE 1—Age Specific Recurrence Rates for 499 Rheumatic Individuals Comprising 5,677 Person-Years

Age	No of Recurrences	Average Person Years	Rate, per Cent
4	16	70.0	22.7
5	30	123.0	24.4

24	3	120.0	2.5
25	3	56.5	5.3
Total 17-25	64	1720.0	3.7

There is a sharp drop in the rates from 1928 to 1931, which reflects the addition to the clinic of a large group of children in whom rheumatic heart disease had been discovered on routine school examination. The elevation in 1932 was due to the transfer to the clinic of patients discharged from the wards following an acute attack of rheumatic fever. It is obvious that in a growing clinic population the different sources from which patients are drawn will influence the average rate of recurrence in the clinic population in any specific year. To prevent erroneous conclusions, it is apparent that data must be inspected for inadvertent bias (chart 3).

It might be expected that the risk of recurrence would vary with the number of previous attacks and the severity of the disease. The rate for the first recurrence after onset was 20.6 per cent. The rate for the second recurrence for those patients who had experienced one recurrence was 18.6 per cent. For those patients who experienced two recurrences the rate for

the third recurrence was 22.1 per cent. It is apparent that the risk for future attacks is not affected by the number of previous recurrences. It was also found that for patients who experienced only arthritis or chorea, alone or combined, the rates were not significantly lower than those observed for children who in

Chart 3.—The rate of recurrence in twelve calendar years (4 to 16).

addition had active carditis, 18.9 per cent and 24.6 per cent, respectively (chart 4).

Unfavorable living conditions are considered to increase the risk of recurrence. It was found that among 59 children living under relatively favorable environmental conditions the rate of recurrence, 22.3 per cent, was not significantly lower than that observed

TABLE 2.—Risk of Recurrence in Relation to Last Rheumatic Attack

Ages	Within 1 Year or More			Following 1+ Years Free			Following 2+ Years Free		
	No. of Recurrences	Average Person-Years	Rate per Cent	No. of Recurrences	Average Person-Years	Rate per Cent	No. of Recurrences	Average Person-Years	Rate per Cent

4-16	463	1202.5	38.7	160	1434.5	11.2

for 123 patients living in a more unfavorable environment, 26.0 per cent (chart 5).

The recurrence rates which have been presented may be used to determine the number of recurrences which should be expected in a random sample of rheumatic patients. It is to be emphasized that the two factors which were found to influence the risk of recurrence at any specific time are the age constitution of the group and the interval of time elapsing since the last attack.

Chart 4.—At left, the risk of recurrence related to the number of attacks. At right, severity of disease and the risk of recurrence.

RECURRENCE RATES IN THE EVALUATION OF PUBLISHED STUDIES

In the majority of recent studies of the relative frequency of rheumatic fever in special groups, attempts have been made to control the observations. However, rarely have alternate experimental and control patients

been selected. It is a common practice to introduce a selective bias by including patients in the control series who are uncooperative, refuse treatment or are dropped from the experimental group for various reasons. In some studies, patients are shifted back and forth from experimental group to control group. Frequently patients are matched for severity of disease or the number of previous attacks. The interval of time elapsing between attacks has not been considered. In many studies the experimental and control groups are not comparable because of differences in age constitution and number of patients. In the majority of the published reports the groups are too small, and conclusions have been based on summated observations.

Although selective factors and inadvertent bias were probably present in the published studies, an attempt was made to compare the number of recurrences expected and observed in the experimental and control groups of six published studies. It was not possible to apply our rates specifically for each age or for varying time intervals in every instance. As far as the data presented could be interpreted, appropriate average rates were applied.⁴ It would be expected that the number of recurrences observed in the control groups would be in close agreement with the number expected, while in the treated groups the number expected would be significantly greater than the number observed. It was found that in the five experimental groups receiving chemotherapy the observed number of recurrences was not significantly lower than expected, with one exception. In

Chart 5.—Relation of environment to the rate of recurrence.

four studies the observed incidence in the control groups was significantly higher than expected, indicating selective or inadvertent bias. The results of this analysis indicate that conclusions as to the efficacy of chemotherapy cannot be drawn from any of these individual studies nor can the results of several studies be summated.

The reported frequency of rheumatic recurrences following hemolytic streptococcus infection is the basis for the prophylactic administration of sulfonamide drugs to rheumatic individuals. The incidence of rheumatic recurrences following hemolytic streptococcus infections ranges from 0 to 82 per cent in the various published studies.⁵ In Kuttner's⁶ large series of rheumatic patients who were under careful observation in a closed colony, only 28 per cent of the children who experienced hemolytic streptococcus respiratory infection had a subsequent rheumatic recurrence.

It is probable that in a clinic population the majority of the children experience hemolytic streptococcus infec-

tion during the season of maximum prevalence of rheumatic fever. If it is assumed that rheumatic recurrences are always preceded by a hemolytic streptococcus infection our recurrence rates may be considered to reflect this hypothesis. When these recurrence rates are applied to a group of rheumatic patients all of whom

COMMENT

The expected rate for a major manifest recurrence of rheumatic fever as defined in these studies should be useful in evaluating observations on comparable groups of rheumatic patients.

Of particular importance is the observation that the rate of recurrence varies significantly with age and the interval of time elapsing since the last attack.

The number of attacks or the severity of the disease did not seem to influence the risk of recurrence.

To avoid selective bias, alternate experimental and control cases should be included for study. To prevent inadvertent bias, the age distribution of experimental and control groups should be comparable and the periods between attacks for the two groups uniform. Such bias in a small series might be responsible for any difference observed.

SUMMARY

1. The average over all risk for a major recurrence of rheumatic fever is 25.0 per cent for patients between the ages of 4 and 13 years, 8.6 per cent for patients between the ages of 14 and 16 years and 3.7 per cent for patients between the ages of 17 and 25 years. The average over all risk for children from 4 to 16 years of age is 20.6 per cent for a major recurrent attack.

2. The over all risk for a major recurrence of rheumatic fever is two to three times greater in any year following an attack than the risk following one or two or more years of freedom from activity, i. e. 20.6 per cent, 10.7 per cent and 6.6 per cent respectively.

3. The risk for the year immediately following an attack is 38.7 per cent in comparison to 11.2 per cent in the year immediately following one year of freedom from a recurrence.

4. The recurrence rate is not significantly different for patients experiencing one, two or three recurrent attacks, i. e. 22.3 per cent, 18.6 per cent and 22.1 per cent respectively.

5. The recurrence rate is not significantly different in patients experiencing arthritis and chorea, with or without active carditis. The severity of the disease did not appear to influence the risk of recurrence.

6. The rate of recurrence in twelve consecutive calendar years, from 1924 to 1935, was not significantly different when sampling factors were not operative.

7. The risk of recurrence is not significantly different among children living under relatively favorable and unfavorable environmental conditions.

CONCLUSIONS

The expected risk for a major recurrence of rheumatic fever at specific ages from 4 to 25 years and for various patterns of disease was defined from the analysis of the records of 499 rheumatic individuals during 5,677 person-years of life experience.

The only factors which were found to influence the risk of future recurrences were age and the interval of time elapsing since the last attack.

Most published studies on the relative frequency of rheumatic fever in experimental and control groups do not appear to meet the basic requirements for adequate biostatistical analysis. Final judgment as to the validity of etiologic concepts and consequent preventive therapy, which are based on these studies, must be deferred.

525 East Sixty-Eighth Street.

Chart 6.—Evaluation of published studies on the frequency of rheumatic recurrences.

had hemolytic streptococcus infections, there should be close agreement between the number of recurrences expected and observed. However, it was found in Kuttner's series of patients, all of whom had hemolytic streptococcus infections, that the number of recurrences observed was significantly greater than the number expected. It is significant that when the rates were applied to Kuttner's total series, in which two thirds

of the group did not have hemolytic streptococcus infections, there was close agreement between the number of recurrences expected and observed. Conclusions as to the role of hemolytic streptococcus infections in precipitating rheumatic recurrences cannot be drawn from these data.

THE DIAGNOSIS OF RHEUMATIC
FEVERT. DUCKETT JONES, M.D.
BOSTON

Numerous factors slowly accruing over the years have resulted in focusing our attention on the problem of rheumatic fever. This would seem logical in view of the fact that it remains one of the important soluble medical problems of our day. Increase in fundamental knowledge of the disease probably accounts for the major increase in interest, along with acceptance by an increasing number of physicians of the public health or community aspects of the disease. Recently small public programs of care have been developed in some states by the Children's Bureau of the U. S. Department of Labor. The legislative authority for such programs has been made possible by federal grants in aid to the states under title V of the Social Security Act. These carefully worked out care programs, along with extensive professional and lay education by many agencies, have played a pioneer role in the stimulation of general interest.

A more immediate stimulus has been the appearance of rheumatic fever among the armed forces in such volume as to constitute a serious medical problem. Epidemiologic data now beginning to appear in the literature indicate that rheumatic fever in the services would seem to be closely associated with epidemics of beta-hemolytic streptococcus infections. Thus, data in the literature on the recurrences of rheumatic fever, especially epidemics of recurrent rheumatic fever in known rheumatic fever and heart disease populations, are found to be pertinent and duplicated in populations of unknown rheumatic fever susceptibility, even in adult age groups. These data are based on reasonably sound observations, since clinical histories or observed illnesses, bacteriologic findings and the results of immunologic tests indicate a close association between rheumatic fever and preceding respiratory infection with beta-hemolytic streptococci, and with cognizance of the many unknown factors and varying elements of susceptibility on the part of the individual. This information offers a rational basis for the development of programs of prevention and care.

Programs of prevention and care (at least at study levels) are hence not only desirable but inevitable and will be insisted on by an informed public. It is therefore fitting that a National Rheumatic Fever Council is in the process of formation, the joint purpose of which is to advocate the extension of public programs of prevention and care, with essential private agency or individual stimulation of study programs and the conducting of studies designed to increase our basic scientific knowledge of the disease.

Despite our increase in knowledge of rheumatic fever, no specific diagnostic test has been forthcoming. This is a distinct deterrent to the advancement of the problem. From the study of the medical literature it is obvious that each observer has his own diagnostic criteria and that these may differ widely. For several reasons the importance of rather strict diagnostic criteria would seem essential at this time, and these may be enumerated as follows:

1. Otherwise the incidence of rheumatic fever may be interpreted as varying greatly whether the data are

collected by surveys, the development of a rheumatic fever register, making the disease reportable, or the study of hospital records.

2. The interpretation of study programs of prevention and care is obviously dependent on such diagnostic criteria.

3. The professional and lay educational programs to date have overemphasized the serious implications of such a diagnosis, so that there is danger in producing often unnecessary and at times violent emotional and psychologic suffering among patients and parents if too liberal criteria are accepted. Granted, incidence figures may be altered inadvisedly. Nevertheless, until diagnostic measures become more specific, prognostic implications altered and reeducation conducted on this basis, there seems little doubt but that we may produce a not inconsiderable number of psychologic cripples. This feature is of especial pertinence to the armed forces.

Hence it is not surprising that the Subcommittee on Cardiovascular Diseases of the National Research Council, interested in the varied aspects of heart disease in relation to the war, has requested a reiteration of the diagnostic criteria of rheumatic fever.

With the understanding that diagnostic criteria must be subject to change as knowledge increases and that for the present it is inadvisable to accept the diagnosis without reasonable assurance of certainty, the various features may be discussed briefly under two headings: the clinical syndrome and the development of rheumatic heart disease. Under these headings one may discuss any feature relative to rheumatic fever, past or present. Some additional features will be mentioned under differential diagnosis and comment.

THE CLINICAL SYNDROME

Major Manifestations.—These manifestations offer the least likelihood of an improper diagnosis. Disagreement would seem to exist largely in the relative importance of the individual manifestations. Few if any clinicians would disagree as to the diagnosis in an acutely ill person presenting a combination of these major manifestations. In only three clinical syndromes is there often any confusion with such a combination of findings. Two of these are relatively rare, while the third is common. They are Still's disease (in children), disseminated lupus erythematosus and the acute form of rheumatoid arthritis. Occasionally long observation is necessary to differentiate these from rheumatic fever, and one must constantly bear them in mind when seeing an acutely ill patient.

1. *Carditis.* Since active carditis is found in all fatal rheumatic fever cases¹ it may be listed as the first major manifestation. Numerous evidences may be found of definite structural or functional cardiac change during acute rheumatic fever. Knowledge of the heart findings prior to the onset is often of prime importance. Incontrovertible evidence of active carditis may be accepted if the patient develops definite cardiac enlargement, significant cardiac murmurs, pericarditis (friction rub) or congestive failure. This would seem to hold at any age if other major manifestations exist. They are at times overlooked in the older patient. In the young patient these findings are usually indicative of rheumatic fever despite the absence of polyarthritis, and, indeed, in children such a clinical picture is not unusual. Doubt will certainly be raised concerning what comprises a significant murmur. It is beyond the scope of this

From the House of the Good Samaritan.
Read in a symposium on "Rheumatic Fever" before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

1. Bland, E. F., and Jones, T. D. Fatal Rheumatic Fever. *Arch. Int. Med.* 61:161 (Feb.) 1938.

report to present the subject in detail. However, a loud, long, apical systolic murmur, widely heard and not varying with position, may be considered significant, as well as any type of diastolic murmur. It is entirely advisable to adhere to the classification and interpretation of heart findings as delineated in the "Nomenclature and Criteria for Diagnosis of Diseases of the Heart" (New York Heart Association, 1940).

Electrocardiographic changes may be demonstrated in many patients if repeated tracings are made. Prolongation of auriculoventricular conduction time (varying limits depending on the age of the patient) is the most frequent finding, but numerous other changes may be encountered (such as inversion of T waves, transient changes in electrical axis during failure, and so on). Cohn and Swift² state that as high as 95 per cent of these patients may show changes. Such changes are noted less frequently in children. While prolongation of the PR interval may be supracardiac in origin (Keith³), the presence of other symptoms make it highly suggestive of carditis, and it is often a diagnostic aid. Various arrhythmias (such as auricular fibrillation) may likewise be found during the acute illness. Sinus tachycardia is usually proportionate to other evidences of illness (carditis, fever and the like), and as a single manifestation it is rarely helpful. Struthers and Bacal⁴ rightly point to the value of the sleeping pulse rate over that of the waking rate.

2. Arthralgia. Migrating polyarthritis is generally considered the classic feature of rheumatic fever. While it is common, especially in the young adult patient, no one symptom offers greater diagnostic difficulty, whether the joint changes are objective or mere subjective complaints. One must remain skeptical where this is the only real clinical finding aside from fever. The diseases are legion in which varying degrees of arthralgia are encountered. It is therefore advisable to search frequently for some evidence of carditis and other major and (as is common) minor rheumatic fever manifestations before accepting arthralgia as being proof of the existence of rheumatic fever. In my experience transient mild polyarthritis, without other diagnostic features suggestive of rheumatic fever or some other medical condition, rarely proves to be a problem of serious import. One must accept, I feel, one exception to this. Knowledge of the epidemiologic disease pattern of the community in which the disease develops may present strong presumptive evidence of rheumatic fever. For instance, if the patient has been exposed to a known beta-hemolytic streptococcus or scarlet fever epidemic, any joint symptoms become more significant. If the patient has had tonsillitis, pharyngitis or even a cold in the past two or three weeks, and serologic tests (such as antistreptolysin determination) indicate a recent hemolytic streptococcus infection, the burden of proof rests with the physician who would not interpret such a syndrome as rheumatic fever, since this represents the usual epidemiologic pattern of the disease. However, in the absence of such findings and other rheumatic fever manifestations, arthritic symptoms should not be considered certain proof of the existence of the disease. Some of the medical diseases to be considered in such circumstances will be given later.

3. Chorea. While chorea is a symptom complex, it is closely related to rheumatic fever. In our experience⁵ about one half of all rheumatic fever patients (young patients) have chorea at some time. Conversely, approximately three fourths of our young chorea patients in time develop other major manifestations of rheumatic fever. This would seem closely to associate the two, and it is a rather satisfying relationship from a diagnostic point of view. Since chorea is rarely seen after adolescence, it is not usually helpful with the diagnosis in adults. However, an occasional adult with questionable rheumatic fever findings give a history of childhood chorea. The presence of definite chorea, associated with questionable signs and symptoms, helps establish a definite diagnosis of rheumatic fever.

4. Subcutaneous Nodules. While such nodules are characteristic, they rarely occur in the early stage of the acute illness, and in a large percentage of instances abundant evidence of carditis exists. Hence, only in rare patients are they helpful from a diagnostic point of view, but more often in the determination of the presence of active rheumatic fever in a person with known previous rheumatic fever or rheumatic heart disease.

5. Recurrences of Rheumatic Fever. Perhaps no feature of rheumatic fever is more striking or more important than the tendency of the disease to recur. Perhaps also no more serious aspect as to prognosis exists. A history of previous definite rheumatic fever or rheumatic heart disease is strong evidence of the existence of the active rheumatic fever in the presence of even mild signs and symptoms. In our experience⁶ about 70 per cent of a series of young rheumatic fever patients had recurrences of the disease within ten years of the onset (the majority within five years), while Roth, Lingg and Whittemore⁷ noted 68 per cent with recurrences in their series.

In summary, a combination of these major manifestations makes a diagnosis of rheumatic fever reasonably certain. One must realize that even with this criterion a statistically small number of cases will prove to have been incorrectly diagnosed, after long clinical observation.

Minor Manifestations.—Since the histologic changes are generalized, it is not surprising that the signs and symptoms are varied. Almost any complaint may be a part of the disease pattern; however, a limited number occur often enough and of such apparent significance as to warrant diagnostic consideration. These may be mentioned with varying degrees of emphasis:

1. Fever. A definite elevation of the body temperature is one of the most common and most variable findings in rheumatic fever. Fever alone, even in the presence of laboratory abnormalities, is insufficient to make a diagnosis of initial rheumatic fever. At the present time fever alone (or often in the presence of an extracardiac or so-called functional murmur) is a common erroneous basis for a diagnosis of rheumatic fever. While fever is helpful, it may be misleading, and other features are usually more important.

2. Abdominal Pain. A frequent occurrence is abdominal pain, the exact cause of which is yet undetermined. Many explanations have been offered. Its occurrence is frequent during evident active rheumatic fever. Of particular interest is the frequency with which it is the initial symptom. This is usually clinically indistinguish-

able from acute appendicitis. I know of no accurate differential feature at this time. It is not unusual for other rheumatic symptoms to occur shortly after the removal of a normal appendix. This may pose a difficult diagnostic problem in known rheumatic individuals. It may be well to state that, since actual acute appendicitis may occur in rheumatic fever patients, decisions as to the need for operation are not easy.

3. Precordial Pain. While this is a common symptom, evidence of carditis is usually found when it is significant. At times precordial pain may suggest coronary involvement. One must remember, however, that mild or transient precordial pain is one of the commonest symptoms of neurocirculatory asthenia, even in the presence of definite heart disease.

4. Rashes. While many rashes have been described in rheumatic fever, it has been my experience that erythema marginatum is by far the most significant cutaneous manifestation. The evidence at hand rather suggests that it might be more properly classified as a major manifestation of rheumatic fever. Further study is needed on this score. Various purpuric manifestations do occur, but they are apparently less frequent than in the past.

5. Epistaxis. Nontraumatic nosebleeds are common in rheumatic fever. They appear to be less severe and less frequent than a decade ago. Their relationship to rheumatic fever is on a clinical basis as yet. In association with other findings they may be useful in the diagnosis.

6. Pulmonary Findings. During acute rheumatic fever various pulmonary changes are not unusual (even consolidation). The clinical and histologic patterns vary considerably. Without other evidence of rheumatic fever, pulmonary changes are rarely diagnostic. In view of their variability, it is advisable to list them as being of minor diagnostic significance.

7. Laboratory Findings. Since at the present time all laboratory abnormalities found in rheumatic fever are nonspecific in character, they are best listed as being of minor significance. The probable more pertinent implication of electrocardiographic abnormalities have been previously mentioned. The development of a microcytic anemia (severe in only a small percentage of patients), an elevated white blood count and an increase in the sedimentation rate of red blood cells are the most common abnormalities. The latter is perhaps the most useful. These tests are of more pertinence in evaluating the presence of active rheumatic fever (in a known rheumatic individual) than is a diagnostic aid. Occasionally rheumatic fever may be active without these laboratory abnormalities. Of especial interest is the frequent normal sedimentation rate in the presence of heart failure.

Numerous other signs and symptoms are encountered. They occur frequently in other diseases or conditions as well as in rheumatic fever. In my opinion they should not be considered as diagnostic aids in the absence of other abnormalities. The more common of these findings are fatigue, pallor, sweating, loss of weight, headache, vomiting (even cyclic), hematuria (more often microscopic than gross), bursitis and pleuritis (friction rub).

In summary, it may be stated that even a combination of these minor manifestations may not be sufficient to make a certain diagnosis of rheumatic fever, although they may be suggestive. It is further suggested that any single major manifestation with at least two of the minor manifestations would seem to place the diagnosis

on reasonably safe grounds. The most common basis for a mistaken diagnosis with acceptance of this criterion would be the occurrence of some degree of arthralgia in the presence of fever and some laboratory abnormality. Here the history of a previous respiratory infection, exposure to a hemolytic streptococcus epidemic and/or the development of hemolytic streptococcus immune bodies would be a helpful and probably conclusive positive aid.

THE DEVELOPMENT OF RHEUMATIC HEART DISEASE

The presence of heart disease of the rheumatic type does not in itself indicate active but previous rheumatic fever. The indications of carditis listed previously are necessary for this interpretation. Rheumatic heart disease (especially mitral stenosis) often develops insidiously. Until we have a diagnostic test for rheumatic fever, the presence of rheumatic heart disease will continue to play an important role in evaluating the disease. The chief ways in which this is helpful may be listed as follows:

1. Minor manifestations of rheumatic fever in the absence of other causation are presumptive evidence of rheumatic fever (even initial) if the patient has rheumatic heart disease.

2. Knowledge of the period in which rheumatic heart disease develops (by previous known normal examination) would clearly indicate a diagnosis of rheumatic fever (mild and even subclinical) during that time. This is helpful in some epidemiologic studies and will doubtless aid in the more certain evaluation of diagnostic criteria.

In the absence of other causation the minor manifestations of rheumatic fever assume increased diagnostic importance in the presence of definite rheumatic heart disease.

DIFFERENTIAL DIAGNOSIS

Time and space do not permit extensive discussion of the differential diagnosis from other individual diseases. Both major and minor manifestations of rheumatic fever occur frequently in other diseases. One must constantly search for clinical and laboratory indications of other diagnoses. The diseases presenting confusion vary considerably. Experiences would differ between pediatricians and those caring for adults. The varied incidence of disease geographically alters the frequency with which some diseases may be confused with rheumatic fever. In a recent comparison of hospital admission and discharge diagnoses Hansen² pointed out that in a distinct majority there was a close agreement. In his group of children abdominal pain simulating appendicitis offered the most common difficulty. Other incorrect admission diagnoses were (in order of frequency) poliomyelitis, osteomyelitis, varied dermatoses and nephritis. It has been previously pointed out that Still's disease, disseminated lupus erythematosus and rheumatoid arthritis must constantly be borne in mind, the last named being the most frequent difficult differential condition in adult patients. It may be pointed out that rheumatic fever and rheumatoid arthritis coexist in a small number of patients. It is surprising that two such common diseases occur so rarely in the same patient. The possible relationship between these two diseases needs further clarification. Months or even years may be required for a definite differential diagnosis. Malingering may present a problem in diagnosis.

Other confusing diseases may be mentioned: tuberculosis, undulant fever, meningococcal septicemia, forms

S. Hansen, A. E.: Diagnosis of Rheumatic Fever, J. A. M. A. 121:997 (March 27) 1943.

of arthritis other than rheumatoid (especially gonococcal arthritis), gout, and even coccidioidomycosis (in limited areas). No attempt has been made to make this list exhaustive.

COMMENT

As already noted, it would seem logical to make a positive diagnosis on rather strict criteria. Until the etiology of rheumatic fever is known or there is a specific diagnostic test, some confusion is inevitable. We may develop more intelligent criteria with careful clinical observations. For instance, the recent syndrome described by Kaiser⁹ may prove to be rheumatic fever, though he has rightly warned against such definite acceptance as yet. The development of rheumatic heart disease by any appreciable percentage of members of the armed services having mild, and even transient, suggestive rheumatic fever symptoms may lead to the more liberal interpretation of possible rheumatic fever symptoms.

The problem of a hereditary susceptibility is also of importance. The high familial incidence of rheumatic fever and susceptibility on the basis of history may and should heavily weigh the interpretation of suggestive manifestations. One hesitates as yet to use this aid for general diagnostic purposes. Recently DeLee, Dodge and McEwen,¹⁰ using polyarthritis as the common clinical feature in comparing children and adult groups, found that residual rheumatic heart disease at the time of hospital discharge was much lower in adults than in children. The elimination of all save one major manifestation as the basis of selection of cases for analysis may lead to false conclusions. It is difficult to evaluate such a varied clinical syndrome as rheumatic fever on the basis of a single sign or symptom. While many observers feel that heart disease is less common in adults with rheumatic fever than in children, it has been my experience that rheumatic heart disease is common to the two groups and without great discrepancy as to incidence.

There has been a strong tendency to consider a satisfactory response to salicylate as a diagnostic aid. The recent revival of interest in salicylate therapy with massive dosages (Coburn¹¹) renews this possibility. One may state that the clinical course of various diseases may be altered to some degree by salicylates. Until additional evidence is forthcoming the amelioration of signs and symptoms by salicylates in questionable cases would not seem advisable to consider as more than suggestive evidence of a diagnosis of rheumatic fever. The evaluation of the effectiveness of salicylate therapy may be rendered impossible unless strict criteria are used in the selection of patients for such study.

In my experience it has been impossible to differentiate any prerrheumatic state.

SUMMARY

For the present, it would seem advisable to limit the diagnosis of rheumatic fever to patients with rather distinct clinical manifestations. It is suggested that the following constitute reasonably certain diagnostic criteria:

1. Any combination of the major manifestations (carditis, arthralgia, chorea, nodules and a verified history of previous rheumatic fever).

2. The combination of at least one of the major manifestations with two of the minor manifestations (fever, abdominal or precordial pain, erythema marginatum, epistaxis, pulmonary changes and laboratory abnormalities).

3. The presence of rheumatic heart disease increases the diagnostic significance of the minor manifestations, when no other cause for these manifestations exists.

Small though probably insignificant errors may be found with these criteria. Numerous clinical entities as enumerated may be confused with rheumatic fever. Clinical observations and, wherever possible, specific diagnostic tests should be applied in any diagnostic problem.

25 Binney Street.

THE ROLE OF THE CARDIAC CLINIC
IN THE RHEUMATIC PROGRAM

DAVID D. RUTSTEIN, M.D.

NEW YORK

The need for the development of community rheumatic fever programs and the importance of the cardiac clinic in such programs has been supported by many clinical and epidemiologic facts. These include difficulties in the diagnosis of rheumatic disease, the chronic nature of rheumatic disease with its impact on family life, the low economic level in which the disease is most prevalent, the wide prevalence of the disease and the complexity of care necessary for the management of patients.

I should like to discuss these individual factors in more detail. The reasons for the difficulty of diagnosis of rheumatic fever have been adequately summarized in the paper by Dr. T. Duckett Jones.¹ I should like to reemphasize the unknown etiology of the disease, the lack of a specific diagnostic test, and the fact that the diagnosis is frequently dependent on the physician's impression of a group of nonspecific symptoms and signs. I have selected these points since they emphasize the great possibility of error in falsely diagnosing the disease in normal persons and the failure to diagnose the disease in the rheumatic patient. Studies conducted by the Cardiac Bureau of the New York State Department of Health indicated clearly that there was a wide variation, i. e. from zero to 13 per cent in the diagnosis of rheumatic disease by the general practitioner in comparable groups of children.² It is a serious matter not to diagnose rheumatic disease when it exists, but it is to be emphasized that it is an even greater tragedy to apply the rheumatic label to a normal child. The symptoms and signs of rheumatic fever are for the most part nonspecific, and the disease is therefore easily confused with a host of other diseases including tuberculosis, anterior poliomyelitis, functional heart disease, influenza or the grip, undulant fever, acute appendicitis, sickle cell anemia and other febrile diseases and inflammatory joint diseases. Emphasizing the difficulty in diagnosis is the fact that initial examinations of suspected cardiac patients in excellent clinics by experts in rheumatic diseases result in one third of the individuals examined being classified as having pos-

2. Rutstein, D. D., and Parker, M. E.: Unpublished observations.

sible or potential heart disease;³ i. e. it is not possible in one third of the cases to determine on one examination whether or not rheumatic disease is present. Therefore it is no surprise that the general practitioner with his many other responsibilities cannot be expected to make a final diagnosis of rheumatic disease in many cases.

The chronic nature of rheumatic disease and the familial prevalence of the disease place a great burden on the family. Patients are prone to have recurrent attacks of rheumatic fever and require special care between attacks. Finally the development of rheumatic heart disease imposes crippling and limitation of activity in a large percentage of cases. This indicates a need for vocational training in a sedentary occupation if the patient is to remain self supporting for a long time.

The fact that more than one person in the same family may become afflicted with the disease contributes to the low economic level in which the disease is most prevalent. The low economic level implies poor, crowded and damp housing, poor nutrition and the frequent occurrence of other diseases in the family. If the rheumatic patient is to be properly handled at home, it is obvious that financial support must be given to the family to improve the environment by obviating those factors which predispose to the disease.⁴ In addition to the patient other members of the family will probably benefit from an improved environment, since they are highly susceptible to rheumatic fever. In certain cases foster home and convalescent home services are necessary, and such services must be supplied.

The magnitude of the problem is great. Where surveys have been conducted, from 0.3 to 4 per cent of the childhood population and from 0.6 to 1 per cent of the young adult population have been found to be afflicted with rheumatic heart disease. This is similar to the prevalence of tuberculosis. Another index of the importance of rheumatic fever is the total mortality from rheumatic heart disease, which, as determined by Hedley in Philadelphia,⁵ amounts to approximately 25 to 30 per hundred thousand annually. Swift⁶ has shown that the reported deaths from rheumatic fever and rheumatic heart disease in New York City in 1938 were 1,105 as compared with a combined total of 247 for whooping cough, cerebrospinal meningitis, measles, diphtheria, scarlet fever and infantile paralysis. In other words, in 1938 there were five times as many deaths from this one disease as from a combination of six common reportable diseases in New York City.

It is evident from the foregoing that the care of most rheumatic patients requires more than medical supervision by a physician. Indeed, it involves the cooperation of the medical and nursing services, the hospitals, convalescent homes, foster homes, public and private welfare agencies, the school systems, housing authorities and public health agencies. If complete care is to be provided, careful interrelated planning by all these agencies must be performed. In surveying this complicated problem, it is evident that the focus for such an organization is the cardiac clinic.

I should like to stress the fact that such community organization is not new. The London County Council, long before the present war, developed the London

Rheumatic Scheme,⁷ which provides a model for such organization. In the so-called Rheumatism Section of the London County Council's Rheumatism Scheme, two series of records are kept: first, a register of all proved cases of rheumatic disease and, second, a file by agency of all the facilities that are available in the community for the care of such patients. Such an arrangement interrelates the activities of the agencies and makes possible the referral of the patient to those agencies which are necessary for his proper care. In upper New York State a survey has revealed that when there is no community program there is a great deal of waste and reduplication of effort on the part of many agencies caring for rheumatic patients.² This could be obviated by the establishment of a cooperative community program.

In the organization of such a program the cardiac clinic should provide the following services: diagnostic, follow-up and case finding facilities, a rheumatic register and an educational program for physicians in the diagnosis and treatment of the disease and for nurses and medical social workers in the part they are expected to play in the management of the disease.

The clinic should serve as an aid to the physician by assisting him in the diagnosis and management of his patients. Clinics can be so established as to assure the physician-patient relationship, at the same time providing the patient with adequate care and the physician with constant guidance in the care of his patient. The physician-patient relationship obtains only in a small number of cases, since most of the victims of this disease, in urban areas, fall into the economic group which makes up the usual clinic population. The patients whose diagnoses are verified in the cardiac clinic would be listed in the cardiac register.

The registry system should not be confused with the usual system of reporting a disease. In the former case, that is the registry system, the diagnoses are verified prior to registration. In the case of a reporting system, cases are filed as reported without verification. The difficulties in diagnosis are so great as to make it practically impossible to evaluate information derived from unverified reported cases. There are also practical difficulties in the institution of a requirement for the reporting of a disease which has previously been unreportable. Chief among these is the understandable objection of the practicing physician to the constant increase in the load of clerical work which expanding public health programs demand of him. This objection might be overcome if it could be shown that the information obtained would be of value and that practical benefits in the form of facilities for the care of patients reported would accrue to the practicing physician. The great amount of effort which would be involved in the institution and maintenance of this system of reporting would, however, have to be justified by the type of information obtained. In the light of past experience it is doubtful at present whether the information obtained by the reporting of rheumatic fever and rheumatic heart disease would justify the effort.

In contrast the collection of verified cases under the registry method offers an approach which will provide accurate information. When that information is complemented by a compilation of all available community

resources for the care of the patient, practical results will accrue to the patient and to the private physician.

Studies such as those conducted at the Boston Lying-In Hospital^{7a} indicate that almost half of a group of adults with rheumatic heart disease had no recollection of preexisting rheumatic fever and most of this group did not know that they had heart disease. The results of such studies demonstrate the great need for a case finding service. It is one of the functions of the cardiac clinic to provide a case finding service. Such a service should be begun by an examination of siblings of known cases in the light of the familial prevalence of rheumatic disease recently emphasized by the studies of May Wilson.⁸

The clinic should provide follow-up services since the disease is a chronic one and because approximately one third of the patients referred to the clinic for diagnosis will require repeated examinations before diagnosis can be made. The follow-up facilities would be used for the establishment of the diagnosis in the questionable cases, for the continued care of patients under treatment by the clinic and for continued consultation with the patients of private physicians.

The cardiac clinic should serve as an educational center for instruction in rheumatic fever and rheumatic heart disease for physicians, nurses and medical social workers. The professional education of physicians would be along two lines. A small group of properly qualified physicians should be trained intensively so that they may be able to assist in the clinic and extend clinic service elsewhere. The general practitioner should be trained primarily in the manifold symptomatology of the disease so that he may lower his threshold of suspicion to the presence of the disease. Since the general practitioner must act as the agency for the initial screening of the cases, he should suspect rheumatic fever in any patient with suggestive symptomatology and refer that patient to the clinic for diagnosis. Training in the nursing aspects of rheumatic fever should be provided to graduate nurses so that they may be able to handle their responsibilities in the management of the disease in an intelligent fashion. Medical social workers should also be trained to know their responsibilities when they are called on to direct the medical social aspects of care of the rheumatic patient.

Public educational programs at first should be limited to that necessary to obtain community support. After the program is well established, education of the public in the symptoms and signs of the disease should be carried on in order that patients may be brought under medical care at the earliest possible moment.

Adequate standards for cardiac clinics have been established. A cardiac clinic should meet standards similar to those established by the New York Heart Association and modified for national use by the American Heart Association.⁹ An inspection of such standards reveals that the facilities of a cardiac clinic are much more than an examining physician and an electrocardiograph. The standards of the American Heart Association provide among others that the clinic have adequate space, be affiliated with the ward service of a hospital and be directed by a physician who has qualifications equivalent to those required by the American Board of Internal Medicine for certification as a spe-

cialist in internal medicine and the subspecialty of cardiovascular disease, or by those required by the American Board of Pediatrics. In children's clinics it is probably desirable to have the general pediatric care of the child supervised by the pediatrician and the cardiac aspects supervised by a qualified cardiologist. The standards also require that provision should be made for consultation service in required specialties, that adequate records be kept and that adjunct services be available, which for the rheumatic patient would provide for fluoroscopy, electrocardiography and laboratory procedures such as leukocyte counts and sedimentation rates. Adequate nursing service should be available. A medical social worker should be attached to the clinic to work out individual problems concerned with utilization of community resources for the benefit of the patient. Indeed, the effectiveness with which the medical social workers perform their jobs will in the final analysis determine the operating efficiency of the clinic.

In summary, then, a community rheumatic fever program is essential if complete care is to be given to patients suffering from rheumatic disease, and the cardiac clinic with an affiliated registry should serve as the focus around which the community rheumatic fever program should be built.

THE GEOGRAPHIC DISTRIBUTION OF HEMOLYTIC STREPTOCOCCI

RELATIONSHIP TO THE INCIDENCE OF RHEUMATIC FEVER

MAJOR ARIE C. VAN RAVENSWAAY

Medical Services Division, Office of the Air Surgeon, Washington, D. C.
MEDICAL CORPS, ARMY OF THE UNITED STATES

Geographic variations in the distribution of hemolytic streptococci and in the incidence of acute rheumatic fever have been generally recognized.¹ Much use has been made of these observations, both as an approach for studying the etiology of rheumatic fever and as a therapeutic answer for those individuals found to be susceptible to this disease. Coburn² has described the results of sending a group of rheumatic children to Florida. This study is well known, but its application has been limited in civilian life by the lack of a nationwide organization to promote its utilization on a large scale.

The concept of a probable relationship between streptococcal infections and rheumatic fever is now widely accepted. The intimate study of this relationship from a bacteriologic standpoint has been made possible by the classification of the hemolytic streptococcus by Lancefield³ and Griffith⁴ into a system of

From the Army Air Forces Rheumatic Fever Control Program. Read in a symposium on "Rheumatic Fever" before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

The data used in preparing this report were gathered at a number of Army Air Forces installations under the direction of the following personnel: Lieut. Wendell C. Allen, Sn. C., Major Warren N. Christopher, Sn. C., Captain Edmundo Felix, Sn. C., Captain Edward D. Freis, M. C., Captain Joseph S. Guts, Sn. C., Major Leslie R. Grams, M. C., Captain Charles G. Jennings, M. C., Captain Arthur C. Jordan, Sn. C., Major Samuel Malamed, M. C., and Captain Roland B. Mitchell, Sn. C.

groups and types and the development of practical methods for their differentiation. The contribution which the Rockefeller Institute for Medical Research is making in serving as a source for the specific grouping and typing serums used in these methods cannot be overemphasized.

My purpose in this paper is to describe geographic variations in the distribution of the component types of group A hemolytic streptococci as observed in Army Air Forces installations and the relationship between these variations and the incidence of rheumatic fever. Reference is made to the use of this information in the management of acute rheumatic fever.

At eight Army Air Forces installations, laboratories for the grouping and typing of hemolytic streptococci are in operation. Credit for the accumulation of material reported in this paper belongs to the personnel responsible for the organization of these laboratories and the development of methods for handling the large amount of bacteriologic material involved in this study. These laboratories have been located so as to represent both areas of low incidence and areas of high incidence of rheumatic fever.

In general, an effort has been made to obtain information in four categories:

1. Hemolytic streptococcus post survey (carrier) rates
2. Incidence of hemolytic streptococci in hospital admissions for upper respiratory disease.
3. The grouping and typing of hemolytic streptococci isolated from patients with scarlet fever.
4. The grouping and typing of hemolytic streptococci isolated from patients with rheumatic fever and from respiratory infections antecedent to rheumatic fever.

The results of these studies have been summarized in the accompanying tables.

GEOGRAPHIC DISTRIBUTION OF HEMOLYTIC STREPTOCOCCI AS DETERMINED BY POST SURVEY

Table 1 indicates the variations in incidence of hemolytic streptococci observed in samples of troops from posts at which the eight laboratories are located. These represent the averages of a series of surveys done at intervals during the period from Jan. 1 to April 21, 1944. The number of cultures involved varies from 245 to 3,222 for the individual posts and total 8,992 for the group. This study indicates for the winter season involved and on a basis of the posts studied that the distribution of hemolytic streptococci throughout troop population is much greater in the Rocky Mountain area and adjacent parts of the country than at posts located in the southern parts of the country.

An analysis of table 1, while indicating great variations in percentage incidence of the hemolytic streptococcus and its component groups and types, shows in general a rather widespread distribution of those different components and no tendency for certain of the types to supplant completely all the others in certain areas. The latter state of affairs would of course be surprising in view of the constant to and fro movement of troops during the process of their training and is in contrast to the epidemic situations which at times arise in relatively isolated groups in civilian life due to a single type of hemolytic streptococcus. This situation is occasionally approached in small posts with relatively stable personnel but has not been observed in this experience in any of the large Air Forces installations engaged in the training of troops.

GEOGRAPHIC DISTRIBUTION OF HEMOLYTIC STREPTOCOCCI IN HOSPITAL ADMISSIONS FOR UPPER RESPIRATORY DISEASE

In table 2 are summarized the results of bacteriologic studies done on patients hospitalized for upper respiratory disease. While it appears that types 19, 17, 30, 3, 1, 36 and 6 are associated with the majority of these infections, at all posts with significant incidence rates a multiplicity of other types are involved.

GEOGRAPHIC DISTRIBUTION OF HEMOLYTIC STREPTOCOCCI IN HOSPITAL ADMISSIONS FOR SCARLET FEVER

Table 3 summarizes the results in 286 cases of scarlet fever. In 229 cases group A hemolytic streptococci were isolated, representing some twelve types. Here again types 1, 3, 17, 19 and 30 are the common types.

THE GEOGRAPHIC DISTRIBUTION OF HEMOLYTIC STREPTOCOCCI ISOLATED FROM PATIENTS WITH RHEUMATIC FEVER

Approximately 1,600 throat cultures have been done on some 400 patients with rheumatic fever at various stages of their disease. The types obtained at individual posts paralleled closely the types observed with respiratory disease and scarlet fever. For the following

reasons these studies are felt to have little etiologic importance and are not presented in tabulated form. In 36 patients pharyngeal cultures were obtained during an upper respiratory infection which preceded by two to four weeks the onset of acute rheumatic fever. An

analysis of the cultures taken after the onset of the latter disease shows that in 28 instances cultures at that time revealed a different type of hemolytic streptococcus. In 4 instances no organisms were recovered (when hemolytic streptococci had been found at the initial examination). In only 6 instances was the same Lancefield type of hemolytic streptococcus isolated at both examinations. Thirty-one strains representing nine Lancefield types were found at the initial culture. If it is assumed that the strains found at the original culture were in large part the organisms responsible for the infection which precipitated the episode of acute rheumatic fever, subsequent cultures must therefore in the majority of instances represent asymptomatic and unrelated cross infections. This thesis is elaborated in table 4. Serial throat cultures taken at intervals approximating seven days in 74 rheumatic fever patients at Buckley Field, Colorado (a post with a high incidence of rheumatic fever), are arranged in columns to

indicate whether the strains listed were isolated from the same individual at the preceding examination or whether they represent a change from this examination.

It happened that in only 1 instance was the same Lancefield type found at the second examination as was isolated at the first, while 37 new strains appeared. This ratio fell with succeeding cultures but further demonstrates the impossibility of obtaining information regarding the bacteriology of the precipitating infection from pharyngeal cultures done following the development of acute rheumatic fever under the conditions which exist at Army posts which have high incidence rates for streptococcal disease and rheumatic fever. A different situation may exist in small static and comparatively isolated groups in which a single type of hemolytic streptococcus may become epidemic.

A study from the Army Air Forces Regional Station Hospital at Davis Monthan Field at Tucson, Ariz., which is located in an area of low incidence of rheumatic fever and streptococcal disease and to which rheumatic

fever patients are sent for convalescent care, is illustrated also in table 4 for comparison with that at Buckley Field. At this post the relative infrequency with which new strains of hemolytic streptococci were acquired is as impressive as is the tendency of the indi-

vidinal strain to persist. Superficially it would appear that newly acquired strains have the ability to supplant those previously present and repetitive infestation to hasten the development of local tissue immunity.

SIGNIFICANCE OF SPECIFIC TYPES OF GROUP A
HEMOLYTIC STREPTOCOCCI

It appears, therefore, that while the typing of group A hemolytic streptococci provides a valuable laboratory method for epidemiologic studies, the ability to produce clinical disease is not a quality inherent or possibly restricted to certain types. Rather, it seems to be a function of the invasiveness and virulence of the specific strain involved and subject to the usual variations encountered in these characteristics of bacteria. It is admitted that in this experience certain types were responsible for the majority of the clinical disease studied, but the fluctuation in incidence of the individual

types at different posts and at the same post at different portions of the winter season indicates the probability that, in other seasons or other geographic areas, types which were of minimal importance in this survey may play predominant roles.

A summary of this bacteriologic experience is presented in table 6. Recognizing the inaccuracies that are inherent in studies of this type which negate the importance of minor differences in numerical values, there is nevertheless a well defined tendency for streptococcal disease to occur with greater frequency at posts with high post survey rates than in those with low rates of this type. However, even at posts with low post survey rates for hemolytic streptococci this organism may be found with frequency in the upper respiratory infection which does occur. A correlation also exists between post survey rates, scarlet fever and rheumatic fever. A comparison of scarlet fever rates and rheumatic fever rates in over two hundred other Air Forces installations confirms the point that rheumatic fever rarely occurs in areas of low frequency of scarlet fever. The thesis may be advanced that, if the streptococcus etiology of rheumatic fever is correct, even in areas of low incidence of streptococcal disease, rheumatic fever

should occur with approximately the same order of relative frequency with which it is found in epidemic areas. This does not occur, however, and such mathe-

mathematical expectations could be filled only if these organisms possessed fixed qualities of virulence and their potential hosts had fixed degrees of resistance.

THE SIGNIFICANCE OF THIS INFORMATION FROM THE STANDPOINT OF MILITARY MEDICINE

Ample evidence is at hand to indicate that a persistence or recurrence of rheumatic activity is related to a persistence or recurrence of the precipitating bacterial infection.⁵ Jones⁶ has clearly shown that an initial episode of rheumatic fever predisposes to further attacks of the disease.

For these reasons the Army Air Forces has adopted the plan of evacuating patients with rheumatic fever to suitable Army Air Forces Regional Station Hospitals, which are picked on the basis of low incidence of streptococcal disease, low incidence of rheumatic fever and suitability for the convalescent care of this disease. At the present time all Air Forces personnel developing rheumatic fever are being moved to such installations when conditions permit.

Whenever practicable this is done by air, which permits transfer by litter at a very early stage of the disease. Approximately 200 cases per month are being moved by air at the present time. In those situations in which air evacuation is not feasible, the movement is made by train at a suitable time in the course of the disease.

It may be appropriate to comment on the overall program for the care of rheumatic fever patients in the Army Air Forces. This disease produces permanent noneffectiveness in several ways. Approximately one third develop permanent cardiac lesions. A second group of significant size develop neuroses usually of a cardiac or neurocirculatory type. A third group are recurrently disabled because of further attacks of the disease.

It is hoped that early diagnosis and proper treatment with early transfer to areas of low incidence will limit the incidence of residual valvular disease. Great care is being taken during the period of activity of the disease not to alarm the patient about the cardiac aspects of the problem. He is then kept in the area of low incidence for a minimum period of six months. During the initial part of the period and following the cessation of the active phase of the disease he receives a suitable period of physical rehabilitation. By concentrating these patients in rather large groups it has been found possible to adapt the convalescent training program more effectually to their specific needs. Following rehabilitation they are given useful employment about the post as a phase of the convalescent program and under medical supervision.

At the termination of the six months period or any additional length of time considered desirable for maximum improvement, the patient is evaluated on the basis of his then existing physical condition and suitable disposition or further military assignment made.

CONCLUSIONS

1. Bacteriologic studies at eight Army Air Forces installations during the period Jan. 1 to April 21, 1944 reveal that group A hemolytic streptococci isolated from cases of upper respiratory disease, scarlet fever and acute rheumatic fever belonged to a multiplicity of Lancefield types.

2. At none of the posts studied was a single epidemic strain responsible for the streptococcal disease observed.

5. Swift, H. F.: *Rheumatic Fever*, in Cecil, R. L.: *A Textbook of Medicine*, ed. 6, Philadelphia, W. B. Saunders Company, 1943, pp. 435-450.

6. Jones, T. D., and Mote, J. R.: *The Clinical Importance of Infection of the Respiratory Tract in Rheumatic Fever*, J. A. M. A. 113: 598-602 (Sept. 2) 1939.

3. At the posts studied bacteriologic data obtained after the development of acute rheumatic fever were not applicable to the preceding upper respiratory infections.

4. An apparent correlation was observed between post survey (carrier) rates from group A hemolytic streptococci, incidence rates for scarlet fever and the incidence of acute rheumatic fever.

THE PREVENTION OF RECURRENCES IN RHEUMATIC SUBJECTS

CAROLINE BEDELL THOMAS, M.D.

Associate in Medicine, Johns Hopkins University School of Medicine
BALTIMORE

Rheumatic fever is a recurrent disease, and the danger of developing permanent organic heart disease increases with every recurrence. These considerations have stimulated a wide search for measures to prevent the recurrent attacks. For years it has been recognized that infections of the nasopharynx, especially sore throat and tonsillitis, frequently precede exacerbations of rheumatic fever. On this account it has been almost universal practice to perform tonsillectomy and adenoidectomy on rheumatic patients in the quiescent stage in the hope of decreasing the frequency and intensity of such infections of the upper respiratory tract and avoiding rheumatic flare ups. However, this hope has not been fulfilled; tonsillectomized patients continue to have rheumatic recrudescences nearly as often as before, although Allan and Baylor¹ have shown that there seems to be less likelihood of rheumatic heart disease developing after tonsillectomy in those who had escaped it up to the time of the operation.

Since the publication of Coburn's² monograph "The Factor of Infection in the Rheumatic State" in 1931 the close etiologic relationship between the beta hemolytic streptococcus and rheumatic fever has become increasingly clear. It is not surprising, therefore, that tonsillectomy is relatively ineffective in forestalling rheumatic recurrences, since beta hemolytic streptococcus infections of the throat continue whether the tonsils and adenoids are present or not. In this regard Coburn³ has emphasized the fact that rheumatic fever is most frequently preceded by rather superficial infections such as mild pharyngitis, in contrast to glomerulonephritis, in which "deeper" antecedent infections such as otitis media and sinusitis are more common.

Because the tropical and subtropical zones are relatively free from the hemolytic streptococcus and from rheumatic fever, Coburn sent a group of 10 rheumatic fever patients to Puerto Rico for six months and noted that no detectable evidence of fresh rheumatic activity occurred in the patients while in Puerto Rico but that definite recrudescences followed shortly after their arrival in New York in the hot summer months. Since that time many physicians have sent their private patients to Florida or Arizona for the winter and spring months, when rheumatic fever is most prevalent in the

Read in a symposium on "Rheumatic Fever" before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

North. This method of prevention of rheumatic recurrences has been fairly effective, but its usefulness is greatly limited by the expense and inconvenience of the undertaking, which must be repeated yearly for five or more seasons if it is to accomplish its object.

In 1936 among the early reports published abroad on the therapeutic value of sulfanilamide was one⁴ which showed that smaller than therapeutic doses of sulfanilamide, administered before the streptococcus had had an opportunity to invade and multiply in the tissues, were effective in preventing beta hemolytic streptococcus infections in mice. This discovery offered the opportunity my associates and I had been searching for, and we immediately embarked on the endeavor to prevent acute hemolytic streptococcus infections and subsequent rheumatic recurrences by giving small daily doses of sulfanilamide to a group of rheumatic subjects over a long period of time.

For four years, from October or November to June, we administered prophylactic sulfanilamide in doses of 1 to 1.2 Gm. a day to a group of adolescents and young adults and compared the results with those observed in an untreated control group of similar rheumatic subjects.⁵ The results, both as regards inhibiting beta hemolytic streptococcus infections and preventing rheumatic recurrences, were strikingly favorable. During the four year study, not a single major attack of rheumatic fever occurred in any patient while taking sulfanilamide prophylactically. In contrast, 15 major rheumatic episodes were observed among the control patients during the same period (an incidence of 10 per cent), and 5 more control patients suffered from acute illnesses which might have been rheumatic in character. None of the patients receiving sulfanilamide prophylactically suffered from any acute beta hemolytic streptococcus infection during the period of treatment in contrast to the control group, and throat cultures positive for the beta hemolytic streptococcus were three times less common among the treated subjects than among the controls.

Coburn and Moore⁶ gave prophylactic sulfanilamide to a group of rheumatic children and observed only 1 rheumatic recurrence among 184 subjects. Other investigators,⁷ working chiefly with children, undertook the same problem, and all have reported excellent results in that rheumatic recurrences have been rare or absent during the period of prophylactic treatment. These reports have now been published in detail, so that I will only summarize them briefly by saying that up to the present in civilian life prophylactic sulfanilamide has been administered to rheumatic subjects for a total of 815 patient seasons over a period of seven years.

Only 8 have had recurrences, an incidence of less than 1 per cent, while the incidence among control groups ranged from 10 to 35 per cent.

During the past winter the United States Navy conducted the most extensive program of mass prophylaxis of respiratory disease and rheumatic fever which has even been undertaken. Capt. T. J. Carter and Comdr. Alvin F. Coburn, who have directed the program, have kindly given me permission to read the detailed reports and to summarize their results. The program was inaugurated in the attempt to reduce the incidence of streptococcal infections, which always account for much loss of time through illness during the late winter and early spring in any center where large groups of young men are living in close quarters, and, especially, to prevent acute rheumatic fever, which had become quite prevalent in some of the training centers. Prophylactic sulfadiazine, usually 1 Gm. a day, was administered to part of the personnel of several training centers from Dec. 1, 1943 to March 1, 1944, with other groups at the same centers serving as controls; about 250,000 men were taking the prophylactic medication, and an equal number were observed as controls.

During this period hospitalization for severe respiratory disease was reduced 80 to 90 per cent. Streptococcal infections were reduced 85 per cent and the

The Effect of Prophylactic Sulfadiazine on the Attack Rate of Rheumatic Fever and Scarlet Fever

Attack Rate	Week of Prophylactic Sulfadiazine Administration				
	1	2	3	4	5
Rheumatic fever.....	87	45	45	19	6
Scarlet fever.....	70	43	0	0	0

incidence of rheumatic fever dropped equally sharply, so that in one center there was only 1 case among the treated group to every 14 cases among the controls. The attack rate of rheumatic fever decreased gradually over the course of several weeks, indicating that prophylactic sulfadiazine interferes with the development of acute rheumatic fever by preventing the antecedent streptococcal infection. If the drug is started during the latent period, after the streptococcal infection has occurred but before the appearance of acute rheumatic fever, the acute rheumatic attack develops regardless of the medication.

The difference between the cause of acute rheumatic fever, which we now conceive of as an allergic state analogous to serum sickness, usually produced by sensitization to the beta hemolytic streptococcus, and the cause of scarlet fever, which is directly produced by infection with the beta hemolytic streptococcus, is shown in the accompanying table.

Here is the incidence of rheumatic fever and scarlet fever week by week after sulfadiazine prophylaxis was started at one of the naval training centers. The lag shown in the tapering off of rheumatic fever as compared with scarlet fever corresponds very well to the conception of a latent period of one to four weeks following the original streptococcal infection before rheumatic fever appears.

During the mass prophylactic sulfadiazine program, meningococcal meningitis practically disappeared, and pneumococcal infections were reduced about 50 per cent. Virus infections were not definitely affected, although there was some drop in the incidence of "catarrhal fever," probably indicating that some grippal

infections are actually caused by streptococci. The program was so efficacious that in March the entire personnel at eight naval training centers were placed on daily doses of sulfadiazine, with reversal of the rising incidence of respiratory diseases among the previously untreated personnel.

Evidence is being accumulated during this program as to the minimal effective prophylactic dose; at present it appears that 0.5 Gm. a day is slightly less effective than 1.0 Gm. a day in adults. Mild drug reactions occurred in 0.3 to 0.6 per cent, but severe reactions were exceedingly rare.

Two other preventive measures which I can only mention briefly are, first, the attempt to immunize rheumatic children by repeated injections of a filtrate of *Streptococcus hemolyticus*. Earlier investigators⁸ were unable to find any evidence that this form of immunization increased resistance to streptococcal infections or rheumatic recurrences. Wasson⁹ and Wasson and Brown,¹⁰ however, reported more than four times as many attacks among the control patients as in immunized subjects, although 10 per cent of those treated still developed rheumatic recurrences. The second method is that of giving salicylates prophylactically, since it had been shown¹¹ that acetylsalicylic acid usually prevents the arthritis of serum sickness and that in patients so treated the production of precipitins against horse serum was inhibited. When doses of 20 to 30 grains (1.3 to 2 Gm.) were given daily over a period of months, the incidence of recurrences did not seem to differ greatly between the treated and the control groups.¹² However, Schlesinger¹³ and later Coburn and Moore¹⁴ gave salicylates daily for one month after the onset of pharyngitis in rheumatic children and found it quite effective in reducing the incidence of rheumatic recurrences. At present neither of these two prophylactic methods has been widely enough used to gain a clear statistical evaluation of their merits. Both are still in the experimental stage, but it seems probable that neither immunization to streptococcus filtrates nor prophylactic salicylates offers nearly the degree of protection against rheumatic recurrences that is afforded by sulfonamide prophylaxis.

Small daily doses of sulfonamides, therefore, seem to be the most effective method of preventing rheumatic recurrences that has yet been found, and I believe that such prophylaxis should be given to all children and young adults who have had one or more unequivocal attacks of acute rheumatic fever. Sulfadiazine is probably the drug of choice, although sulfanilamide affords just as efficient protection and is not significantly toxic when low doses are given. It may be that sulfamerazine will some day replace the other drugs on

account of its slower rate of excretion, but no large scale study of sulfamerazine prophylaxis of rheumatic fever has yet been carried out.

Since the dose of 1 Gm. daily of sulfadiazine used in the Navy program corresponds extremely closely with our dosage of sulfanilamide, in contrast to the 2 or 3 Gm. daily used by some investigators, and since excellent protection is afforded by this dosage, there seems no reason to give more, and unless further evidence to the contrary is obtained it would usually be unwise to give less either to children or to adults. In the Navy, for purposes of convenience, two 0.5 Gm. tablets were given at once every twenty-four hours, but since the drug is largely excreted in a few hours 0.5 Gm. every twelve hours offers greater protection, at least theoretically.

As soon as a patient has reached a satisfactory convalescent stage following acute rheumatic fever, that is, when he is free from arthritis, fever and other symptoms in the absence of salicylates, prophylactic sulfonamide should be started. In my experience it is not necessary to wait until the sedimentation rate is entirely normal. It is important to start prophylaxis before the patient returns to his home environment from hospital or convalescent home, to avoid immediate reinvasion of the nasopharynx by the beta hemolytic streptococcus. In an effort to avoid toxic reactions, I should like to suggest starting most patients on 0.5 Gm. a day for three weeks, during which time the patient should be protected from close contact with crowds, after which the dose should be increased to 1 Gm. a day.

The patient should then continue to take 1 Gm. a day, day in and day out, summer and winter, year in and year out, for at least five years, and probably longer in younger children, if the patient is to be safely steered through the period when recurrences are most frequent. This seems a long time, but in my experience patients become thoroughly accustomed to taking it, and, rightly or wrongly, ascribe an unusual state of well being to the drug, so that they are loath to stop. They no longer suffer from most of the bacterial infections, although they still may have the common cold in mild form, influenza and the virus diseases of childhood. Several of my patients have noticed the complete abatement of various minor ailments, such as recurrent erysipeloid infections of the face or otitis media, from which they formerly suffered. One of my patients has taken prophylactic sulfanilamide successfully for nearly eight years!

How great is the danger of toxic reactions? Statistically, it is very small, as has been convincingly shown by the United States Navy program. Mild reactions such as transient skin eruptions, which were annoying but not dangerous, developed in from 3 to 6 men out of 1,000, while serious reactions, such as agranulocytosis and exfoliative dermatitis, were exceedingly rare among the 500,000 men who have received prophylactic sulfadiazine at one time or another during the last six months. Since the risk of serious toxicity during treatment is much less than the chance of untreated rheumatic subjects developing recurrences leading to serious rheumatic heart disease, we should certainly treat the rheumatic patient to the best of our present therapeutic knowledge with prophylactic sulfonamide therapy.

What can the physician do to safeguard a patient to whom sulfonamide prophylaxis is given? First, he should see that the patient is in the best possible physical

condition, with adequate diet, and without unusual factors affecting his health or environment during the early weeks of treatment. It was noted in the Navy that the number of mild toxic dermal reactions was nearly four times as great among new recruits who received prophylactic sulfadiazine while they were being immunized to typhoid, tetanus and so on as among seasoned personnel. Second, the dose may be started at 0.5 Gm. a day, increasing to 1.0 Gm. a day after three weeks. Third, parents or patient should be instructed to report any rash or sore throat immediately, without further dosing with sulfonamides by themselves or by any other physician. Fourth, total leukocyte counts should be made frequently during the early weeks of treatment, since agranulocytosis rarely if ever develops after the first six weeks and usually occurs between the end of the second and the fourth week.

It is to be hoped that before the war is over studies conducted among large groups of men in the armed forces may point the way toward reducing toxic reactions to the vanishing point. In conclusion I should like to express the belief that, in spite of the difficulties involved, the increasingly widespread use of prophylactic sulfonamides will bring tremendous advance in the problems of rheumatic fever and rheumatic heart disease.

Johns Hopkins Hospital. _____

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. WILSON AND ROSE LUBSCHETZ.
DR. JONES, DR. RUTSTEIN, MAJOR VAN
RAVENSWAAY AND DR. THOMAS

DR. JOHN R. PAUL, New Haven, Conn.: In trying to determine where the hemolytic streptococcus belongs among the several factors responsible for rheumatic fever, one has the advantage of the experience of the Army during the last three years, in which epidemics of rheumatic fever have been reported in this country for the first time. Such epidemics have put a new light on the subject. Although there have been plenty of isolated cases of rheumatic fever in which it has been difficult to trace any preceding evidence of hemolytic streptococcus infection, I think it is safe to say that there have been no records of epidemics without preceding epidemics of hemolytic streptococcus infection. Dr. Wilson's analyses of recurrence rates are important to those who must try to plan postconvalescent therapy. A program such as Dr. Thomas has outlined may be based, for instance, on the rates at which recurrences may be expected. Dr. Jones has rightfully laid great stress on diagnosis of the acute disease. Is the patient rheumatic or not? This is a big decision if it determines whether or not to embark on four, five or six years of prophylactic sulfonamide therapy. The point that Dr. Rutstein made about the role of the cardiac clinic in establishing the rheumatic register deserves comment. There has been much agitation lately to make rheumatic fever a reportable disease. It has been tried in various parts of the country with varying success. Difficulties are that if rheumatic fever is to be reportable one must first give reasons for making it reportable, one must define diagnostic criteria and one must have facilities for taking care of patients who are reported. If, however, there is a cardiac clinic and it maintains a register, it can function as a local clearing house for cases of rheumatic fever and can be concerned with therapeutic facilities and data on prevalence as well. Major van Ravenswaay has shown what a tremendous opportunity the Army has to outline the geography of this disease. Standard methods can now be employed in attempting to determine how prevalent hemolytic streptococcus types are in various areas and what their correlation with rheumatic fever has been. I should like to ask him whether he has recorded the prevalence of another complication or manifestation of hemolytic streptococcus infection, namely acute nephritis.

COLONEL W. PAUL HOLBROOK, M. C., A. U. S.: The present knowledge regarding the etiology of acute rheumatic fever may be illustrated by describing certain observations made concerning this disease in the Army Air Forces. When a large number of men from all parts of the country are thoroughly mixed and then distributed by posts, some will be located in areas of low incidence and some in areas of high incidence of acute rheumatic fever. Those in areas of low incidence will show a low rate of group A hemolytic streptococcus upper respiratory tract infections as contrasted to a high rate among those in areas of high incidence. Although the total numbers of cases in the two groups contrast sharply, it may be pointed out that upper respiratory disease associated with group A hemolytic streptococci does occur in areas of low incidence of rheumatic fever and proportional incidence rates of the latter disease are not found. As a further result of the shuffling of troops, persons with a family history of rheumatic fever who perhaps are hereditarily susceptible are stationed as frequently in areas of low incidence as in areas with a high incidence of this disease. Since the susceptibles do not develop rheumatic fever in areas of low incidence, it seems that susceptibility cannot be considered the sole explanation. There is evidence to suggest that climate and the invasiveness of the strains of hemolytic streptococci involved may also be important factors. I do not know what all the etiologic factors are, nor do I know how they are interrelated. We can all agree that probably a combination of factors is required to produce acute rheumatic fever in an epidemic form.

DR. STANLEY GIBSON, Chicago: Two years ago Dr. Brown and I at the Children's Memorial Hospital undertook a study of sulfonamide prophylaxis in the recurrence of rheumatic fever. We selected 50 children who had been in the hospital during the previous year with a rheumatic episode. All these children were under the age of 12, so that if I understood Dr. Wilson correctly I believe both as regards age and as regards the time of their previous episode they should be candidates for recurrence of rheumatic fever. About 44 of these children went through the experiment. The other 6 failed to cooperate. None had to be left out because of their inability to take the 1 Gm. of sulfanilamide daily which was given to them. The drug was kept up from about the 1st of October until the 1st of July the following year. During that period we had no single recurrence of a rheumatic episode that we could recognize clinically. We had used up about all of our children who had had an episode during the preceding year, so that we did not attempt a control group. At the end of the first year we checked over these children and found that only 3 out of our 50 children without sulfonamides had had a recurrence of rheumatic fever. However, 1 of these children had a severe recurrence and is much more crippled as a result of that rheumatic recurrence. The second year is almost up and the 1st of July we shall check over our children again. We haven't our figures complete now as to how many recurrences have occurred during the second year. I know this much: One who had had relatively little cardiac involvement previously came back into the hospital about two months ago with a fulminating carditis and promptly died. I do not know whether the statistical method is completely applicable or not in these instances. If the sulfonamides do protect, it was terribly important for that child to have them. I should like to ask Dr. Thomas in her closing discussion to state whether or not any instances of death have occurred from recurrent rheumatic infection in an individual receiving sulfonamides. I am sure I do not know from our small study whether they protect or whether they do not.

DR. JOHN W. SCOTT, Lexington, Ky.: Valuable as the cardiac clinic is, there is, I think, danger of magnifying its function in this connection. Its function should be that of the counselor rather than of the arbiter. That the last word must be said by a specialist in cardiology or by a specialist in anything else is to overstandardize the profession and to contribute to the decay and not the upbuilding of the practice of medicine.

DR. J. D. KEITH, Nova Scotia: I should like to ask Dr. Thomas why she would not use the sulfonamides.

DR. PAUL F. DWAN, Minneapolis: Because of the complex nature of this disease—complex mostly because of the chronicity and tendency to recurrence and because of the fact that

we are dealing with growing children—many ramifications in this matter have been discussed. We know that we must maintain proper environment for these children, that they must receive the best possible medical aid and that their education must be maintained during the convalescent period. The magnitude of this problem, in my mind, places it beyond the scope of any agency, whether governmental or private. It is becoming increasingly obvious that some aid must be given to the families of rheumatic children and to the physician who is trying to handle the cases, because of the expensive nature of any home or hospital care. The disease is difficult to handle in the home because it is almost impossible to maintain discipline and proper bed rest for the period of time necessary. It may be in this field that governmental or social aid would be of its greatest value. The various rheumatic fever programs which have been set up have proved to be of great value in the communities where they have been established. Most of them have worked on the basis of giving a temporary lift to the situation and maintain themselves only in a manner of assisting the patients over the period of his acute illness and convalescence and turning him back to his private physician. I feel that this is as it should be and that there is no need for a complete socialization of rheumatic fever cases to the extent that the private physician is eliminated from the picture; the problem is so great that any such management would be inefficient and might be deleterious to the patient and the patient-physician relationship.

Dr. MAY G. WILSON, New York: I think that perhaps I can answer Dr. Paul's question by using our rates on Dr. Gibson's study. We would have expected that between 4 and 8 patients in his group would have a recurrence during the time of treatment. I have analyzed every published study, and this is the first one that would give me any reason to believe that chemotherapy prophylaxis is effective in preventing rheumatic recurrences. In the other studies to which we applied appropriate rates we found that there was no evidence of a significant difference between the treated and the control groups with the exception of one study, and in that study the control group showed bias. Our purpose in the paper we presented was not to discourage chemotherapeutic prophylaxis in rheumatic fever research but to point out that future studies must take into account the natural history of the disease. If studies are planned properly, we should have our answer to the efficacy of chemotherapeutic prophylaxis in rheumatic fever in civilian life.

Dr. T. DUCKETT JONES, Boston: I think that Dr. Dwan is assuming that those interested in the development of rheumatic programs are trying to take the problem out of the hands of the physician. It is entirely a mistaken conception. It is high time that the medical profession in general assumed enough interest in the disease to develop community programs. We need not get into argument about whether or not we are going to take the thing out of the hands of local physicians: that is irrelevant. Perhaps the most pertinent of the armed service's materials so far as evaluation is concerned has been presented today. I wish that Major van Ravenswaay had not compared the rheumatic fever incidence with scarlet fever, as it is notoriously unreliable when compared with known incidences of streptococcal diseases in various parts of the country. I think there could have been a closer correlation. I can certainly agree with him in general. Until complete data of all these studies are available, I think it is foolhardy to accept the sulfonamides or any other means of prophylaxis as certain and sure. I feel that it is rather unsafe for the future of our knowledge of rheumatic fever to accept in as unequivocal a way as Dr. Thomas has data which are not completely analyzed and when she has not had an opportunity to go over everything. It may ultimately result in holding up knowledge of rheumatic fever for a good many years. I am not sure that the association between the hemolytic streptococcus index and rheumatic fever is the whole story, and I think that we must keep open minds until such time as more evidence is available. I am not against prophylaxis with sulfonamides, but I believe that their use should be distinctly experimental at the present time and not be given to everybody in the country.

Dr. DAVID D. RUTSTEIN, New York: My paper was written from the point of view of the needs of the rheumatic patient. I did not say that the diagnosis could be made only by those

qualified by the specialty boards. I did state that the American Heart Association standards require the cardiac clinic director to have qualifications equivalent to those of the indicated specialty boards. Specialty board qualifications were not promulgated by public health agencies but were established under theegis of the American Medical Association. I also did not say that the general practitioner should transfer his patients to the clinic, but I did say that the clinic should offer guidance to the general practitioner in the diagnosis and treatment of his patient. The inability of the general practitioner to diagnose this disease adequately is a matter of fact and not of opinion. The data presented resulted from an analysis of 21,293 school records divided among twenty-nine school systems. In eight of the twenty-nine not one diagnosis of rheumatic fever had been made, while there was one school in which 13.1 per cent, or 1 out of every 7 pupils, were labeled as rheumatic. Other experiences support these data. Dr. Thomas's recommendations would influence the nature of the community program, but Colonel Holbrook indicated that the military experience does not necessarily apply to civilians. I should like to make three points which support that statement: 1. The medical services in the armed forces have complete control over their patients, and by giving sulfonamides to all groups the initial attack of rheumatic fever may be prevented. The civilian program must be limited to the prevention of recurrences unless sulfonamides are given to every child. 2. The armed forces have facilities for the determination of the absence of rheumatic activity. This must be determined before sulfonamide prophylaxis is inaugurated. In many civilian communities such facilities are not easily available. 3. Constant supervision of patients receiving sulfonamides is necessary; this may be difficult to accomplish in the civilian population. I agree with Dr. Jones that there is an unquestionable relationship of the hemolytic streptococcus to rheumatic fever and that the exact relationship is not clear. The evidence for that relationship is based on post hoc ergo propter hoc reasoning, and it is well to remember that thus far Koch's postulates have not been fulfilled.

MAJOR A. C. VAN RAVENSWAAY, M. C., A. U. S.: Dr. Paul inquired about the incidence of acute glomerular nephritis at Army Air Force installations in relationship to the incidence of acute rheumatic fever. We have been surprised to observe that the incidence of acute glomerular nephritis has been extremely low, although it has been impossible to get any statistically significant information. Major Frank Foster of Buckley Field tells me that during the last winter season he saw over 350 cases of acute rheumatic fever and 4 cases of acute glomerular nephritis. In regard to Dr. Jones's comments about the controls which were used in the sulfadiazine prophylaxis studies both by the Army Air Forces and by the Navy, I hope that at some future time we shall have a chance to go over with Dr. Jones the exact nature of the controls which were used and which we and others believe were quite satisfactory. In regard to the relationship of the hemolytic streptococcus to the etiology of rheumatic fever, the Army Air Forces have placed such emphasis on that because it offers one positive approach to the problem. Obviously it is much easier to do something about the hemolytic streptococcus than it is about the genetic background of individuals in high incidence areas of rheumatic fever.

Dr. CAROLINE BEDELL THOMAS, Baltimore: I think Dr. Dwan and Dr. Gibson will agree that it is difficult to set up a valid experiment when working with a small group of rheumatic patients. Dr. Wilson rightly assumes that the alternate case method is best when working with large groups. We divided the control and treated groups on the basis of age and previous numbers of rheumatic recurrences so that they would roughly approximate each other. Dr. Kuttner's study at Irvington House, to which Dr. Wilson referred, certainly is the best clinical civilian study on this subject. She divided 108 children into two groups of 54 which were closely intermingled. One group was given sulfonamide prophylaxis and the other was not. Among the sulfonamide treated series, 1 developed streptococcal infection and none developed rheumatic fever. Among the controls, 37 developed streptococcal infection and 14 developed rheumatic recurrences. These results are significant and clearcut. In every such study carried out under any

circumstances, the incidence of rheumatic fever has decreased in the treated series. The studies which the armed forces are making will result in a more statistically valid series of controls than we have heretofore had. Dr. Jones, I have carefully read the original reports of the United States Navy, and the statements which I made today were based on the report of one of the largest stations, in which the controls were carried out company by company. Answering Dr. Gibson's question whether any deaths from rheumatic fever have occurred during sulfonamide therapy, 3 of the children studied in the Bellevue clinic died of advanced heart disease while receiving prophylaxis. Dr. Dodge always considered that they were given sulfonamides in a very advanced stage of the disease; whether or not there was progressive activity at the time sulfonamides were started is questionable. The patients were afebrile but had Aschoff bodies in the myocardium at autopsy. In answer to Dr. Keith, salicylates should be withdrawn during convalescence to be sure the rheumatic process has fully subsided. Later, when the condition of the patient is fully quiescent, if there is any virtue in giving salicylates together with sulfonamides I see nothing against it, although I have had no experience in that problem.

Clinical Notes, Suggestions and New Instruments

PERFORATION OF THE INTESTINE DUE TO TYPHOID

CAPTAIN AARON A. DUBROW
MEDICAL CORPS, ARMY OF THE UNITED STATES

A Negro soldier aged 25 was admitted to a battalion medical regiment hospital on Oct. 25, 1942 complaining of chills and chilly sensations, headache, abdominal pain, diarrhea alternating with constipation, nausea and vomiting, backache and general malaise. Abdominal pain was generalized. Headache was supraorbital and very severe. The patient stated that about ten days previously he had experienced an episode of diarrhea which was followed by an episode of constipation. At the time of admission he was again having a diarrhea, averaging four to eight watery stools each day, associated with some tenesmus. He denied the presence of bloody or tarry stools. He stated that he had had very little appetite the previous two weeks and on several occasions he had episodes of nausea and vomiting. He seemed to tire easily on the slightest exertion, always seeming to be fatigued, and had experienced insomnia and restlessness.

The family history was essentially negative. The past history was also negative, the patient stating that he had always been in good health. His army immunization record showed that he had received all the required vaccinations and immunizations, including typhoid, smallpox and tetanus.

The patient at the time of admission appeared moderately ill; he was well developed, and was ambulatory. He was well oriented and cooperative. The temperature was 104 F. by mouth, pulse rate 88 and respiratory rate 22 per minute. The skin was hot and dry, and there was no evidence of any rashes or skin eruptions. The pupils were equal and reacted well to light and in accommodation. There was definite conjunctival injection but no icteric discoloration. The ears and nose were normal. The tongue was coated and thick, and there was a very foul odor from the mouth. The teeth were in fairly good condition. The chest was clear on inspection, auscultation and percussion. On examination of the circulatory system the heart sounds were of good quality; no murmurs were elicited. The blood pressure was 114/80.

The abdomen was somewhat distended and tympanitic. There was generalized tenderness with some increased tenderness in the right lower quadrant. No masses or fluid wave were present. There was some tenderness in the splenic area, but the spleen was only questionably palpable.

The extremities were normal. On neurologic examination the reflexes were found to be somewhat hyperactive but were otherwise normal.

The laboratory findings at the time of admission revealed a white blood cell count of 3,500 with 60 per cent polymorpho-

nuclear leukocytes and 40 per cent lymphocytes. The urinalysis revealed the presence of some albumin, but the microscopic examination was negative.

The patient's stay in the hospital was rather stormy. His temperature rose daily to 104-105 F. with no remissions to normal, the lowest temperature being 101 F. The pulse rate ranged from 80 to 100 beats per minute and the blood pressure ranged from 100-110 systolic to 60-80 diastolic. The chest was normal at various examinations except for occasional rales at the bases. Abdominal pain and distention continued. The tenderness continued to be generalized, although there was usually some increased tenderness in the right lower quadrant. The patient became very apprehensive. He had occasional periods when he appeared to be somewhat disoriented and confused. Anorexia became even more evident. In short, he presented the picture of an acutely ill patient who was showing no progress.

Because of the limited laboratory facilities, no extensive laboratory work could be done in this forward area. His blood picture continued to show a leukopenia, the white blood cell count dropping as low as 2,000 with 50 to 55 per cent lymphocytes. The urinary picture remained essentially the same, although he began to show positive tests for varying amounts of acetone and diacetic acid. A satisfactory stool examination could not be done.

The treatment was essentially symptomatic and palliative. Sulfaguanidine had no appreciable effect. However, the diarrhea subsided, to be followed by a tendency to constipation. Quinine therapy also had no effect.

On November 2 the patient suddenly began to have very severe abdominal pain. On examination shortly after he appeared acutely ill, with hippocratic facies; he lay in bed with his knees drawn up. He was obviously in shock and

appeared to be very disoriented. The temperature had dropped to 97 F. but soon began to go up again. The pulse was rapid and thready. The respirations were shallow and increased in rate. The abdomen was decidedly rigid and with extreme generalized tenderness. At this time the patient was considered to have an acute condition of the abdomen possibly due to typhoid or one of the dysentery group of organisms.

He was given 1,000 cc. of 10 per cent dextrose in isotonic solution of sodium chloride preoperatively in an attempt to combat shock. A laparotomy was performed through a low midline incision, ether being used by the open method as the anesthesia. When the peritoneal cavity was opened free fluid of a serosanguineous nature as well as a pronounced injection of both the small and the large intestine were observed. This injection became increased as the terminal ileum was approached. The terminal ileum showed the presence of four perforations ranging from $\frac{1}{2}$ to $1\frac{1}{2}$ inches in diameter. The last perforation was about 1 inch from the ileocecal valve. About 10 inches of the ileum was resected. Because of the patient's poor condition it was thought inadvisable to perform any type of anastomosis at this time. A double barreled ileostomy was performed, a modified Mikulicz technic being used. Five grams of sulfanilamide powder was instilled intraperitoneally. The abdomen was closed tightly, no drains being used. The patient received plasma and fluids intravenously during and after the operation.

For the following three days he received 4,000 to 5,000 cc. of fluids intravenously. He began to show slow but progressive improvement. The ileostomy functioned well. His temperature dropped considerably, ranging in the vicinity of 101 F. Owing to the inadequacy of proper nursing care, evacuation to more suitable surroundings was considered advisable. On the fourth postoperative day he was evacuated to a rear zone by plane.

Fig. 1.—Section showing one of the ulcers with pronounced lymphocytic infiltration. This photomicrograph was taken through the eyepiece of the microscope.

Blood cultures, Widal tests and other laboratory procedures could not be done in this locality. However, various cultures and blood specimens were sent to laboratories in less forward zones. A Widal test taken on the day of operation was negative. However, a Widal test taken three days later was positive in high dilutions. A blood culture was positive for *Eberthella typhosa*. A cultured specimen as well as a smear of the ulcers revealed a pure culture of *Eberthella typhosa*. Urinary specimens were not sent for bacterial examination.

The pathologic examination of the microscopic section revealed that it was of a segment of small intestine showing one margin of a deep perforated ulcer. The mucosa and ulcer margin was sharply demarcated. The ulceration extended through all coats of the intestine. The base of the ulcer consisted of necrotic tissue, debris, fibrin and neutrophils.

The submucosa showed hyperplastic lymphoid tissue consisting mainly of lymphocytes. Also present were many plasma cells, many large mononuclear cells and scattered eosinophils. The mononuclears showed pronounced phagocytosis of tissue debris, cells and erythrocytes. A few cells were in mitosis. The muscularis was edematous and was infiltrated with lymphocytes, eosinophils, large mononuclear cells and a few neutrophils. On the serosal surface there was evidence of peritonitis. The surface was covered with an exudate consisting of fibrin, neutrophils and a few mononuclear cells.

The microscopic appearance of this lesion was compatible with the diagnosis of perforated typhoid ulcer of the intestine with peritonitis.

The differential diagnosis prior to surgery was very difficult. At the time of his admission, dengue fever and bacillary dysentery were very prevalent in the immediate and surrounding areas. The confusing abdominal picture frequently presented by other fevers and sometimes by dengue fever could not be ruled out prior to surgical intervention. Amebic dysentery was also not too common. Botulism was also to be considered, owing to the large amount of canned foods being used at that time. The acute and sometimes severe gastroenteritis and enterocolitis of undetermined etiology that were not too infrequently

The fact that the patient had received his three immunizing injections of typhoid vaccine also helped to complicate the case. Apparently the immunity accorded by the vaccines was only temporary or he had not been able to build up sufficient antibodies to afford him sufficient immunity. Had the infectious organisms been of a very virulent strain, it seemed probable

Fig. 3.—Section showing the debris, necrotic tissue, fibrin and neutrophils at the base of the ulcer.

Fig. 2.—Section showing the base of the ulcer with debris, necrotic tissue, fibrin and neutrophils. There is also present the pronounced lymphocytic infiltration of the submucosa as well as many plasma and mononuclear cells.

seen were also considered. No cases of typhoid or paratyphoid had been reported. There were no other similar cases in his organization or in any organization in the immediate area. As a result of all this a truly complicated picture presented itself, and up until actual surgical operation no accurate diagnosis could be made. The entire picture was made doubly difficult by the limited laboratory facilities.

that other members of the same unit would also have contracted the disease. All the soldiers had been using the same water sources, and no fresh milk or other fresh dairy products were available in this area. The water had been chlorinated in the usual army manner by means of a Lyster bag.

The follow-up of this case was rather interesting. Convalescence was further complicated by a bronchopneumonia. This was satisfactorily treated. The patient was transferred again to a general hospital, where an operation for a secondary closure and anastomosis was subsequently performed. As far as is known now the patient has made a satisfactory recovery.

PENICILLIN TREATMENT OF A CASE OF TULAREMIA WITHOUT EFFECT

LIFUTENANT COLONEL ALLEN I. JOSEY
MEDICAL CORPS, ARMY OF THE UNITED STATES

This case of apparently tick borne, pneumonic type of tularemia is reported with comments as to the effect of treatment with penicillin and sulfadiazine.

A soldier aged 28 years was admitted to O'Reilly General Hospital June 5, 1944, complaining of headache, malaise and fever of four days' duration. The patient's past history was entirely noncontributory. For two weeks prior to admission he had spent his furlough time on a farm in southeastern Missouri. There had been no contact with any wild animals, but he was bitten a number of times by ticks during the week prior to the onset of his present illness. On June 2 he first noticed generalized headache, weakness, chilly sensations and fever. During the following three days these persisted and he developed a slight amount of mucoid, blood tinged discharge from the nasopharynx, a slight cough and generalized aching in the chest.

On examination he appeared acutely ill, his temperature was 105 F., the pulse rate was 108 and the respiratory rate was 26.

From the Medical Service, O'Reilly General Hospital.
The laboratory reports included in this communication were done in the Laboratory Service, O'Reilly General Hospital, Springfield, Mo., and in the Laboratory of the Seventh Service Command.

There was a superficial ulceration about 0.25 cm. in diameter just above the inner portion of the right clavicle. On the anterior pillar of the right tonsil there was a similar ulcer. Neither of these ulcers was indurated or painful and there was no associated lymph gland enlargement. Over a small area at the left lung base there were a moderate number of fine and medium rales without any change in breath sounds or percussion note.

During the next twenty-two days the condition of the patient was febrile, with temperature as high as 104.5 F., which then fell by lysis during the next four days to normal. During the first three weeks he remained acutely ill. The bloody mucoid discharge from the nasopharynx subsided within seventy-two hours. Dyspnea was persistent for about two weeks, but there was only slight cough and very little mucoid expectoration. The two small superficial ulcers remained unchanged for about ten days and then healed spontaneously. At no time were there any palpably enlarged lymph glands. There was a spread of the physical signs compatible with bronchopneumonia over the entire left lower lobe and part of the right lower lobe of the lungs. On the ninth day of the disease a pleural friction developed at the left lung base followed by an accumulation of a moderate amount of fluid in the left pleural space, which was tapped on the eleventh and sixteenth days with aspiration of 60 and 350 cc. of serosanguineous fluid. As the temperature returned to a normal level there was symptomatic improvement, and by the thirtieth day of the disease the patient was gaining strength rapidly and the only apparent residual of the disease was evidence of moderate pleuritis at the left base.

The urine contained a slight amount of albumin and a few granular casts during the febrile period. There was no anemia of note at any time. The white blood cell count was 8,400 on admission and varied from 5,300 to 11,400, with a moderate increase in neutrophils during the febrile period. Repeated blood cultures were negative. Agglutination against *Pasteurella tularensis* was negative on the tenth day of the disease, but it became positive 1:40 on the eleventh day and positive 1:2,560 by the twenty-third day. It is of interest that there was an associated rise in his agglutination to *Brucella abortus* to 1:320. Fluid removed by thoracentesis on the eleventh day of the disease was injected into the peritoneal cavity of a rabbit. This rabbit died four days later and showed evidence of splenic enlargement with areas of focal necrosis. Material obtained from the spleen of the animal was injected into a second rabbit, which died five days later. *Pasteurella tularensis* was cultured from the spleen of the second rabbit, and microscopic sections of the liver and spleen of the same rabbit showed findings typical of tularemia. X-ray examinations of the chest substantiated the physical findings of the pneumonia and serofibrinous pleurisy.

Effective treatment was symptomatic and supportive in nature. The patient had been given sulfonamide by his local physician before admission to the hospital. Owing to the obscurity of the diagnosis sulfadiazine, which had been given for thirty-six hours following admission, was discontinued. On the eighth day of the disease penicillin was begun in doses of 20,000 Oxford units intramuscularly every three hours. This was continued for thirteen days with a total dosage of 1,900,000 Oxford units. Shortly thereafter the temperature curve, which had been spiked in character, became more level but the mean elevation was not reduced. There was no effect noted on the symptomatology or physical signs. On the ninth day of the disease it was decided to reinstitute sulfadiazine therapy, and sufficient drug was administered to maintain a blood level between 5 and 8 mg. per hundred cubic centimeters in the circulating blood. This also was apparently ineffectual and was discontinued on the twenty-first day.

SUMMARY AND CONCLUSIONS

A case of apparently tick borne pneumonic type tularemia ran the usual course of the disease, with fever for twenty-six days. The course of the disease was not affected by the intramuscular injection of 1,900,000 Oxford units of penicillin over a period of the eighth to the twenty-first day of the disease. Administration of sulfadiazine from the ninth to the twenty-second day of the disease was also ineffectual.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN E. SMITH, M.D., Secretary.

MANNITOL HEXANITRATE.—Mannitol Nitrate.—Nitromannite.— $C_6H_8O_5N_2$ M. W. 452.17.—An explosive compound formed by the nitration of mannitol, a sugar alcohol. Its stability at ordinary temperatures is such that it may be used commercially but it is distinctly less stable than nitroglycerin at 75 C. Its use for pharmaceutical preparations is only in admixture with carbohydrate substances in dilutions corresponding to 1 part of mannitol hexanitate to 9 or more parts of carbohydrate. In such dilutions mannitol hexanitate is non-explosive. Mannitol hexanitate has the following structural formula:

Actions and Uses.—Mannitol hexanitate exerts the vasodilator action of the nitrite ion (NO_2), causing a relatively persistent relaxation of smooth muscle, especially that of the smaller blood vessels. This relaxation causes a fall in blood pressure, occurring within fifteen to thirty minutes and lasting four to six hours. It also relaxes the coronary vessels and frequently provides relief from the pain of angina pectoris, although too frequent dosage may cause such a fall in blood pressure that the blood flow continues to be inadequate in spite of the vasodilatation. It has no direct effect on the myocardium.

Toxic effects include the formation of methemoglobin (which should constitute a warning concerning the use of nitrites by anemic persons), rise in intraocular tension, headache, increase in intracranial pressure and cardiovascular collapse. Treatment of severe untoward effects includes cessation of therapy with the drug, administration of oxygen, transfusions for shock, removal of drug from the stomach and other supportive measures such as lowering of the head and elevation of the limbs. Vasopressor agents should not be used in the presence of cardiovascular collapse, as they may aggravate the condition.

Dosage.—Mannitol hexanitate may be administered in 15 to 30 mg. doses at intervals of four to six hours. Occasionally this dose may be exceeded, but careful watch of the blood pressure and the patient should be kept at all times so that the development of undesirable side effects and the patient's tolerance may be noted. The dosage should be kept at a minimum compatible with satisfactory results. Patients with extensive arteriosclerosis may not present reductions in blood pressure and, as in other instances, if no reduction occurs, medication with mannitol hexanitate should be discontinued.

Tests and Standards.—

Mannitol hexanitate tablets are partially soluble in alcohol and in ether (mannitol hexanitate) and are partially soluble in water (lactose). To a powdered tablet of mannitol hexanitate add one drop of diphenylamine test solution; a characteristic blue color is formed.

The residue obtained in the assay given below melts between 100 and 108 C. (Caution: The mannitol hexanitate used in this test may explode on percussion. The operator must be protected by a glass screen while determining the melting point.) It is insoluble in water and soluble in alcohol and in ether. It may be recrystallized from hot alcohol in the form of characteristic long needles in regular clusters.

Transfer an accurately weighed portion of powdered tablets, containing about 0.25 Gm. of mannitol hexanitate, to a glass stoppered Erlenmeyer flask and extract the powder with 25 cc. of ether; decant the extract through a dry filter paper into a tared dish and repeat the extraction five times; evaporate the combined filtrates to 3 cc. at a temperature not exceeding 35 C. and allow the remaining solution to evaporate spontaneously. Dry the residue over calcium chloride in a vacuum desiccator for eight hours and weigh the mannitol hexanitate; the amount of mannitol hexanitate found corresponds to not less than 93 per cent nor more than 107 per cent of the labeled amount.

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Tablets Mannitol Nitrate: 16 mg. and 32 mg. Each tablet contains not less than 93 nor more than 107 per cent of the labeled amount of mannitol hexanitate and also contains at least 9 parts of carbohydrate by weight.

SATURDAY, OCTOBER 21, 1944

SULFONAMIDE AND PENICILLIN THERAPY IN GAS GANGRENE

The present war has renewed interest in the therapy of gas gangrene, with special emphasis on the possible efficiency of the newer chemotherapeutic agents. Bliss and her associates¹ therefore inoculated mice intramuscularly with the specific organism and tested the therapeutic value of various sulfonamides given orally or by means of local injection. None of the sulfonamides showed a high degree of activity in combating experimental *Clostridium welchi* infection, but better results were obtained with local injections than with oral administration. Sewell and his associates² made similar experiments on dogs and were also unable to abort gas gangrene with sulfonamides but were able to prolong life.

About the same time McIntosh and Selbie³ treated 24 mice within three hours after experimental infection with *Clostridium welchi* by local injection of 34 Oxford units of penicillin and reported 100 per cent survival. Following this encouraging lead, Hac⁴ and her associates of the Department of Obstetrics, University of Chicago School of Medicine, made detailed therapeutic assays of tyrothricin, zinc peroxide, sulfanilamide, sulfapyridine, sulfathiazole, sulfadiazine and penicillin, tested either alone or in combination. Mice were inoculated intramuscularly with 0.25 cc. of a 1:4 dilution of an eighteen hour brain-broth culture of highly virulent *Clostridium welchi*. With this dose most of the untreated mice showed evidence of a generalized reaction (chills, hematuria and so on) within six to eighteen hours, death occurring in about twenty-four hours in 85 per cent of the cases. Necropsy revealed an edematous hemorrhagic area frequently extending upward to

the axilla and downward to involve the entire leg. In practically all animals that survived, an extensive lesion which tended to slough persisted at the site of inoculation.

In the therapeutic test 0.25 cc. of a solution of the chemotherapeutic agent was injected either subcutaneously into the subinguinal region of the infected leg or into the opposite leg. The injection was made at varying times, such as half an hour before inoculation, at the time of inoculation or from one to three hours afterward. Of 404 untreated controls 85 per cent developed hematuria and 365 died, a survival rate of 9.7 per cent. In the parallel prophylactic test (therapy given half an hour before inoculation) the survival rate was increased to 96.6 per cent by a single 50 mg. dose of sulfadiazine and to 88 per cent by a single injection of 250 Oxford units of penicillin. Sulfadiazine was thus apparently the prophylactic agent of choice.

When the therapy was delayed till one hour after inoculation, however, the condition was reversed. The survival rate was 92 per cent with 250 Oxford units of penicillin, as contrasted with only 48.3 per cent survival with 50 mg. of sulfadiazine and 20 per cent survival with 50 mg. of sulfathiazole. When the therapy was delayed till three hours after inoculation, the survival rates were reduced to 38 per cent for penicillin and to an average of 10 per cent for the two sulfonamides. Within the limits of the experimental error, the two sulfonamides were useless in this delayed therapy, the control survival being 9.7 per cent. As a result of immediate penicillin therapy the hematuria rate was reduced to zero. In penicillin therapy delayed for one hour the hematuria rate was 42 per cent, increasing to 60 per cent if delayed two hours and to 85 per cent if delayed three hours.

Hac treated groups of mice with a single subcutaneous injection, using varying doses of penicillin given at the time of inoculation. The 9.7 per cent survival rate in untreated controls was increased to 54 per cent survival as a result of 5 Oxford units of penicillin, 73 per cent survival with 15 Oxford units and a maximum of 98 per cent with 500 Oxford units. The smallest dose of penicillin (5 Oxford units) was thus superior to the optimal dose of sulfadiazine or sulfathiazole. This superiority was shown in other ways. When treated animals died, the average period of survival was longer with penicillin than with the two sulfonamides. Penicillin was also much more effective than sulfadiazine or sulfathiazole in minimizing toxemia and tissue damage and in accelerating local tissue repair. After successful penicillin therapy the lesion at the site of the inoculation is usually healed in ten to eighteen days, as compared with twenty-two to thirty-six days after successful sulfonamide therapy. With small doses of penicillin, subcutaneous injection in the infected leg gives better results than injection into the

opposite leg. With large doses of penicillin, however, local and distant subcutaneous injections are equally effective.

Encouraging as these results may be, Hac asserts that neither sulfonamides nor penicillin given alone or in combination will prove to be clinically effective in human cases unless combined with "adequate surgical procedure."

REGIONAL ILEITIS

Regional ileitis has been receiving more attention ever since Crohn and his associates¹ first described it in 1932. In a recent system of gastroenterology by Bockus,² the whole chapter is brought up to date; aside from correlated statistical data, comparatively little has been added to the original description of the disease.

Pathologists agree that the distinguishing features are: 1. Hypertrophy and thickening of the bowel wall, usually confined to some one localized stretch of the mesenteric small intestine, most frequently the terminal ileum, and varying in extent from a few inches to several feet. A bizarre feature of the disease is its occasional tendency to attack more than one segment of the bowel, leaving the intervening segments intact. The process may involve the colon down to the sigmoid. 2. Resultant narrowing of the bowel lumen. 3. Hyperplasia of the mucosa, frequently with ulceration. 4. Perforation with localized or general peritoneal involvement and the establishment of internal or external fistulas. This train of events is usually preceded by hyperplasia of lymphatic tissue and an obstructive lymphedema. Microscopically the appearance is highly mimetic of tuberculosis; but all attempts to demonstrate tubercle bacilli or any other causative organism, including the virus of lymphogranuloma venereum, have failed. The counterpart of the disease has not been observed in animals.

The diagnosis rests on symptoms so complex and varied as to create an almost invariable hazard. Crohn's original classification of symptoms is valid today, and we shall always be on safer ground if we bear in mind that the course of the disease may follow any of four patterns: (1) that of acute intra-abdominal disease, resembling most frequently acute appendicitis; (2) that of ileocolitic diarrheal disease; (3) that of chronic intestinal obstruction with supervening acute obstruction; (4) that of fistulous (external or internal) formation. Differential diagnosis demands consideration of acute appendicitis, bacillary dysentery, acute perforative peritonitis, intestinal obstruction and cancer of the bowel.

Treatment is usually surgical. If the patient is seen in the acute stage and the abdomen is mistakenly opened

for appendicitis, the consensus seems to be that the time-old maxim of "let a sleeping dog lie" should be followed and the abdomen closed without drainage. In the chronic cases the methods of treatment are either resection of the diseased segment of bowel or of side-tracking it (by ileocolostomy or by some similar procedure). Search should always be made for so-called skip areas of bowel, distant from the region under immediate surgical attack; but even if these are found and cared for adequately there are, unfortunately, an appreciable number of postoperative recurrences. Since the etiology is not known, methods of prevention are not available. In those cases in which it may be suitable to apply purely medical treatment, this should follow, in general, the lines established for the treatment of ileocolitis.

Such are the short and simple annals of a perplexingly interesting and, on occasion, a fulminantly dangerous disease. Before 1932 ileitis was unknown as a distinct entity, yet within the following seven years more than 500 cases had been reported. This reminds us that appendicitis, for all practical purposes, was unknown until after Fitz's work in 1886 and that duodenal ulcer likewise did not appear on the medico-surgical stage until the early nineteen hundreds. Curiosity is no less aroused by the present day novelty of intervertebral disk displacement. How long will regional enteritis baffle the search for its cause?

FOUR YEARS OF WAR SURGERY

Some people, including some physicians, hold the notion that the calamity of war is offset, at least partly, by war's contribution to the advancement of medical science in general and of surgery in particular. Improvements in the medical service to our wounded men in the present war are due chiefly to the principle of advanced surgical units, to more rapid ground and aerial transportation, to the use of sulfonamides, to more liberal recourse to blood and plasma transfusions and to plaster immobilization of soft tissue wounds. Major General Mitchiner¹ asserts that this improvement is not as great as one would like to believe, especially in the prevention and control of sepsis. Mitchiner says that "the self-congratulatory coma into which some of our 'specialist' colleagues have allowed themselves to lapse is almost without justification." He feels that the slightly wounded should be given precedence of treatment.

These cases constitute 60 to 70 per cent of war wounds; if promptly and adequately treated near the battle front, most of these men can be returned to the front line. In World War I a large number of wounds

¹ Mitchiner, Philip H.: *Thoughts on Four Years of War Surgery—1939 to 1943*, *Brit. M. J.* 2:37 (July 8) 1944.

were from bullets, whereas those seen in the present war are mainly lacerated wounds of a severe type, the mortality from which is much higher. In the bombing casualties of aerial warfare some 60 per cent of the patients die either as a result of the actual injury plus blast or soon after from hemorrhage and shock due to the severity of the wound inflicted.

While admitting the great part played by the Blood Transfusion Service, Lord Mitchiner feels that there is a tendency to overevaluate blood transfusion to the detriment of older and simpler methods of resuscitation and wound treatment such as hot sweet fluids by mouth, warmth and morphine. Furthermore, the risk of septic infection from administering blood transfusion on the field of battle and in the street during an air raid is considerable. Blood or serum should not be given intravenously farther forward than the advanced dressing station on the field of battle, the sick bay when this is functioning adequately in a ship, and the first aid post during an air raid. He also feels that there is a tendency to give large quantities of blood unnecessarily and wastefully. Secondary suture of war wounds is safer and is to be preferred to primary suture. Mitchiner stresses that these principles are not new, that all emanated from the practice of surgery of the war of 1914 to 1918 and from earlier wars. Even the closed plaster technic, for which credit is given to Trueta, was practiced in the Crimean War by Pirogoff.

Infection of wounds has been much modified and the danger greatly reduced by the use of sulfonamides. However, Mitchiner warns again that excessive and indiscriminate use of these drugs is not without risk. Many patients show an idiosyncrasy to drugs of this group, while certain organisms react only to certain types. He believes that the treatment should be carried out in close cooperation with a bacteriologist. Any dose over 15 Gm. applied externally may produce toxic and even fatal results even in cases in which the fluid intake can be kept up by both intravenous and oral administration for the three days subsequent to the use of a sulfonamide. Sulfonamides, therefore, are not a panacea for all infections but may actually be deleterious and even dangerous. Their use, as a general rule, should be discontinued promptly in cases which show no constitutional improvement or fall of temperature in forty-eight hours. Penicillin, on the other hand, is not toxic and far surpasses all other antiseptics. Its action is most dramatic on the staphylococcus and gonococcus. Its use, however, may entail a drastic revision of surgery of wounds, for apparently it acts best in the presence of pus and in cases in which it is applied locally. Lord Mitchiner concludes that the surgical procedure has not altered greatly since World War I, although the type of wound has altered somewhat owing to the use of more lethal explosives and missiles.

This realistic evaluation by a competent authority is not to be construed as a confession of disappointment or failure but rather as a timely warning against the dangers of complacency and wishful thinking.

Current Comment

EFFECT OF TRAVEL ON THE INCIDENCE OF ABORTION

Diddle¹ reports a study on the incidence of abortion among a group of pregnant women who journeyed and a group who maintained a sedentary existence during the period of gestation. The particular naval hospital and dispensary from which the data were collected served all obstetric dependents of the Navy, Marine Corps, Coast Guards and Army personnel. The geographic position of the clinic was particularly favorable to this type of study. The area concerned is an island 127 miles away from the mainland of the Continental United States and is connected with the latter by means of a rough asphalt and coral highway and a system of bridges. The road in places is corrugated with transverse humps. In order to commute to and from the nearest railroad, 170 miles away, it was necessary for all women to go by bus or car over this course. For a period of observation limited to sixteen weeks there were 289 women who journeyed and 467 who did not. A smaller group, in which 200 women did not journey and 110 did, permitted observation month by month for a longer period. Of the 289 travelers who toured before the end of the fourth month 16, or 5.6 per cent, had untimely births as contrasted to 84, or 17.9 per cent, occurring among the control or sedentary series. Based on the 179 protocols where the distances covered were known definitely, 46 (25.7 per cent) were multigravidas and 37 (20.6 per cent) parous. A careful analysis of all the factors involved suggested to the author that neither the distances covered and the method of travel nor the time of the month at which a journey was taken revealed any significant differences in the incidence of abortion. The results of these observations, although involving a small group, suggest that travel by car or bus over the rough stretch of highway covering the keys and over modern roads and by train in the states did not increase the incidence of abortions among travelers as opposed to nonjourneying women. Transportation alone probably did not predispose to abortion, except in 1 case in the series: the woman had ridden a motorcycle a few hours previously. Journeying perhaps had facilitated an interruption of gestation where intrinsic and extrinsic factors were already in action. The principal argument against traveling is that it entails the possibility that an expectant mother may need medical care wherever trouble may arise and with such resources as are present.

MEDICINE AND THE WAR

ARMY

BRIG. GEN. LEON A. FOX RECEIVES TYPHUS COMMISSION MEDAL

Brig. Gen. Leon A. Fox has been awarded the Typhus Commission Medal for his work as director and field director of the United States of America Typhus Commission in the Middle East and Mediterranean areas, and specifically for his direction of the Typhus Control Project of Naples in December 1943, which brought that epidemic under control within a month. The citation accompanying the award reads "For exceptionally meritorious service rendered first as director and later as field director of the United States of America Typhus Commission. In charge of the commission's activities in the Middle East and North Africa since March 1943, General Fox increased the extent and value of investigations and control of typhus fever in Egypt and in other Mediterranean countries. In positions of high responsibility his opinion and counsel had important influence on both medical affairs and international relationships. On missions to London he further cemented and strengthened British and American effort and policy for operation with civil affairs in this country and abroad. In December 1943 General Fox was placed in charge of the campaign against the outbreak of typhus fever at Naples, at a time when the disease had reached epidemic proportions and was a threat to military operations. Securing full cooperation from military and civilian agencies, he organized a vigorous attack on the disease, employing all the modern principles and methods for combating typhus. So effective was the work done under General Fox that the epidemic was brought under control within a month. The achievement in controlling this epidemic of typhus at Naples and in southern Italy ranks as one of the greatest triumphs of modern preventive medicine." Dr. Fox graduated from the University of Cincinnati College of Medicine in 1912 and has been in the service since June 1917.

THREE EGYPTIAN HEALTH OFFICIALS HONORED FOR TYPHUS WORK

The War Department announced recently the award of the United States of America Typhus Commission Medal to three Egyptian health officials for their cooperation with our scientists in the study of typhus fever. The citation of Dr. Ali Towfik Shousha, under secretary of state for health of the Egyptian government, reads:

"For meritorious service in connection with the work of the United States of America Typhus Commission. From the time of the arrival of the commission's group in Cairo early in 1943, Dr. Shousha has taken great personal interest in the activities of the commission. He has entered wholeheartedly into the cooperative projects which have been established. Through his sound advice and administrative capacity he has furthered all the investigations and control work done by the commission in Egypt."

The following is the citation of Dr. Abdel Hamid Sadek, director of the section for epidemic diseases of the Egyptian government health department:

"For meritorious service in connection with the work of the United States of America Typhus Commission. By his interest and tireless efforts Dr. Sadek greatly facilitated the whole program of field investigations and the control of typhus fever in Egypt. From these activities, information and experience were gained for the improvement of epidemic typhus control in all areas."

The citation of Dr. Mahmoud Abou-Demerdash, director of the Egyptian government hospital for infectious diseases, is as follows:

"For meritorious service in connection with the work of the United States of America Typhus Commission. Through the interest and cooperation of Dr. Demerdash, wards and laboratory buildings were made available to the United States of America Typhus Commission at the Fever Hospital in Cairo in 1942. As the clinical and laboratory investigations increased with the encouragement and aid of Dr. Demerdash, improved facilities were provided at this hospital in 1944. Dr. Demerdash has taken great personal interest in the work of the members of the commission with patients suffering from typhus fever. He has given expert advice and training based on his experience with the disease and has materially aided the commission's study of typhus fever in Egypt."

LIMITED SERVICE OFFICERS EXAMINED FOR OVERSEAS DUTY

Because of the urgent need for Medical Corps officers for overseas assignment, a survey is being made of all those in the army service forces who are now on permanent limited service with a view to their possible reclassification. Many, it is felt, can be assigned to communication zone installations overseas, where they can perform duties similar to those in the zone of the interior. Medical Corps officers will not be considered disqualified for overseas service if they can be expected to render effective professional service without appreciable risk of aggravating physical defects or if they have histories of defects which are not demonstrable and have not resulted in hospitalization while in service.

ARMY'S RECONDITIONING PROGRAM MAY INFLUENCE CIVILIAN HOSPITALS

Major Henry B. Gwynn, of the Reconditioning Division of the Office of the Surgeon General, recently stated that the strides being made in the operation of the Army reconditioning program will probably lead to radical changes in the civilian hospital of the future. Civilian hospitals, capitalizing on the progress made by the Army's reconditioning program, will probably include motion picture theaters, gymnasiums, public address systems and areas for physical and occupational therapy in their buildings of tomorrow. Anticipating the objection of increased costs in such a program, it was pointed out that the Army is finding that hospitalization time is curtailed from 10 to 33½ per cent as a result of reconditioning. If this estimate holds true even to some extent in civilian practice, Major Gwynn stated, the lower incidence of complications and the shortened convalescence at home before resuming normal activities will more than pay the additional cost.

The prospects for the adoption of this reconditioning program by civilian hospitals will depend on public opinion and the attitude of the medical profession, Major Gwynn said, and ideas which have been in vogue for several hundred years will be changed only when the facts justify it.

FIVE HUNDRED MEN COMMENDED FOR PART IN TESTS OF NEW GAS OINTMENT

Five hundred officers and enlisted men were recently commended by the Chemical Warfare Service of the Army Service Forces for voluntarily exposing themselves to lethal gases in order to test a new anti-gas protective ointment. As a result of these tests, during which men entered gas filled chambers and contaminated areas, medical officers and research scientists have conclusive evidence that the M5 protective ointment, or "gasproof makeup kit," will be effective in the event that the enemy resorts to gas warfare. The commendation stated that the men "participated beyond the call to duty by subjecting themselves to pain, discomfort and possible permanent injury for the advancement of research in protection for our armed

forces." Among the volunteers were 40 soldiers of Japanese ancestry now serving with United States forces.

The men subjected to the gas chamber tests were protected by gas masks and liberal quantities of the new ointment. Others tested the substance by entering ground areas which had been contaminated with lethal agents. In order to minimize the danger to the personnel, tests were made only after exhaustive experiments with the ointment. None of the volunteers suffered any ill effects.

CIVILIAN NURSES NEEDED FOR ARMY HOSPITALS

Registered nurses who are professionally but not otherwise qualified for commissions in the Army Nurse Corps are needed for employment under Civil Service in army hospitals.

Registered nurses more than 45 years of age who are not physically qualified for commissions or whose home responsibilities prevent them from applying for commissions are eligible for these positions.

Urgent need for commissioned nurses in the overseas theaters, where their skill often means the difference between life and death for an American soldier, has resulted in a shortage of qualified nurses in hospitals in this country. Simultaneously, increased numbers of patients are being sent back to this country from the battle fronts.

Civilian nurses wishing to avail themselves of the opportunity for service in army hospitals may work in hospitals near their homes. They may live in government quarters or may reside at their homes, provided adequate transportation is available to and from work. Working hours for civilian nurses in army hospitals often are longer than the standard forty-eight hour week. The salary is \$2,190 a year, on a forty-eight hour week basis, but, if circumstances require overtime employment, additional pay may be authorized.

Qualified nurses interested in this type of employment can get full information at the army hospitals nearest their homes. Employment will be completed through Civil Service channels.

SEVERAL HUNDRED DENTAL OFFICERS TO BE RELIEVED FROM ACTIVE DUTY

A recent announcement by the War Department stated that several hundred dental officers will be relieved from active duty with the Army shortly, permitting their return to private practice. The following priority is established for the release of officers in replacement pools or elsewhere whose services can be spared:

1. Officers not physically capable of doing a full day's duty operating at a dental chair.
2. Limited service officers requiring special consideration as to climate, diet or type of work or who are qualified for assignment in the United States only.
3. Officers whose relief from active duty can be accomplished under current War Department policies governing officer personnel generally.
4. Officers selected by the Surgeon General who can be released with least detriment to the service. This category will be used, after exhausting all others, to make up the number required to be released to reduce an existing surplus of dental officer personnel.

ARMY HOSPITALS MAY EMPLOY NURSES BEFORE COMMISSIONING

Graduates of the U. S. Cadet Nurse Corps who have taken their Senior Cadet period in army hospitals and who have applied for commissions in the Army Nurse Corps may be hired as civil service appointees by army hospitals subject to the law of the state in which each hospital is located. Appointments will not exceed six months' duration. This step has been taken because of the shortage of qualified nurses and of the delay in commissioning due to the fact that state board examinations, a prerequisite for a commission, are frequently not given for some time after the graduation date.

MAJOR TEGTMEYER NAMED MOST CITED DOCTOR

Major Charles E. Tegtmeyer, formerly of Hamilton, N. Y., five times decorated by the Army Medical Corps, has been named the most frequently cited former staff member of New York's voluntary hospitals. In nearly three years of service Dr. Tegtmeyer has been in the North African, Sicilian and Italian campaigns. Twice wounded in action, he is the recipient of the Purple Heart, Bronze Star, Silver Star, Legion of Merit and Distinguished Service Cross "for conspicuous gallantry in rescuing and saving the wounded." Dr. Tegtmeyer graduated from Columbia University College of Physicians and Surgeons, New York, in 1935.

FIRST PHYSICAL THERAPIST AWARDED LEGION OF MERIT

First Lieutenant Metta L. Baxter, PT, of Los Angeles, now stationed with the 21st General Hospital in Italy, is the first physical therapist to be awarded the Legion of Merit. Her citation reads "for exceptionally meritorious conduct in the performance of outstanding service." Lieutenant Baxter is a graduate of Kansas State College, Manhattan, and received her physical therapist certificate from the Army Medical Center, Washington, D. C.

CAPT. ROBERT E. WOLF MISSING IN ACTION

Capt. Robert E. Wolf, formerly of Shreveport, La., has been reported missing in action since August 10. Dr. Wolf has been a battalion surgeon and has been in the army for two years. He went overseas last October. Dr. Wolf graduated from the University of Arkansas School of Medicine, Little Rock, in 1940 and entered the service Aug. 22, 1942.

FLIGHT SURGEONS' ASSISTANTS

A class of seventeen flight surgeons' assistants completed the six weeks course in aviation medicine at the School of Aviation Medicine, Randolph Field, Texas, September 15. These men are trained as specialists in assisting flight surgeons in the selection, care and maintenance of the flier. Brig. Gen. Eugen G. Reinartz, U. S. Army, is commandant of the school.

ARMY AWARDS AND COMMENDATIONS

Major Albert J. Bajohr

The Bronze Star Medal was recently awarded to Major Albert J. Bajohr, formerly of Flushing, N. Y. His medal was won on Bougainville, where battle surgery was performed night and day in an underground hospital. Dr. Bajohr graduated from George Washington University School of Medicine, Washington, D. C., in 1933 and entered the service April 2, 1941.

Captain Vincent S. Cunningham

For his gallant conduct in combat at Humboldt Bay, Dutch New Guinea, Capt. Vincent S. Cunningham, formerly of Long Island, N. Y., was awarded the Silver Star. The citation accompanying the award read "As a result of enemy bombing an ammunition and supply dump was set afire. With utter disregard for his own personal safety, and constantly in danger of being hit by shrapnel from exploding ammunition, Captain Cunningham set up an aid station near the fire and labored all night and until the next afternoon taking care of and gathering all casualties that could be collected." Dr. Cunningham graduated from New York University College of Medicine in 1935 and entered the service in June 1942.

Captain Fred A. Dry

The Silver Star was recently awarded to Capt. Fred A. Dry, formerly of Allentown, Pa. His citation reads "During the initial days of combat, severe casualties were sustained from German fire. During this time Captain Dry worked incessantly

to ease the treatment and removal of the wounded. Refusing suggestions that he remove his first aid station to a place of safety, he performed his duties as close to the front lines as possible. On several occasions, although he had not slept for days and with utter disregard for his own safety, he evacuated wounded from exposed front line positions and entered dangerous areas rather than order his men into areas subjected to heavy enemy fire." Dr. Dry graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1941 and entered the service in July 1942.

Major Dalton C. Hartnett

The Legion of Merit was recently awarded to Major Dalton C. Hartnett. The citation accompanying the award reads "He performed outstanding services as Flight Surgeon, 3d Photographic Mapping Squadron, from Feb. 20, 1943 to March 28, 1944. During this period, while serving the squadron on three continents in zones ranging from the arctic circle to the tropic of Capricorn, he maintained the health of the command at a very high level. He planned and personally conducted courses of instruction for the prevention of disease and the preservation of health. His untiring vigilance, initiative and personal check of all individuals of the command, by day and by night, resulted in maintaining 98.3 per cent of the unit available for duty." Dr. Hartnett graduated from St. Louis University School of Medicine in 1940 and entered the service June 30, 1941.

Major Jay Paul Roller

The Oak Leaf Cluster to the Silver Star was recently awarded to Major Jay Paul Roller, formerly of Luckey, Ohio. The citation accompanying the award reads "In Sicily in August 1943 a part of the Regimental Communications Section was sent forward to establish an advance communications switch. The leading vehicles of the convoy were hit by enemy artillery fire and mines, killing four and severely wounding eight of the

enlisted men riding in front vehicles." Major Roller was called and went forward to the area being subjected to heavy enemy artillery and mortar fire to administer medical aid to the eight wounded soldiers. During the course of this outstanding devotion to duty he lost several of his own medical personnel as the result of German S mines. Notwithstanding this he continued on to the completion of his tasks throughout the night. On this occasion and countless others he demonstrated such gallantry and disregard for self in the performance of hazardous missions that his courage and devotion to duty are a constant inspiration to the officers and men of his regiment." The citation accompanying the Silver Star award appeared in THE JOURNAL Dec. 4, 1943, page 908. Dr. Roller is a graduate of the University of Louisville School of Medicine, 1939. He entered the service Jan. 5, 1941.

Captain Byrne M. Daly

Capt. Byrne M. Daly, formerly of Jackson, Mich., was recently awarded the Bronze Star for "meritorious service in actual combat while serving with the third (Marine) division on the Fifth Army front in Italy." The citation which accompanied the award read "Capt. Daly served as battalion surgeon without an officer assistant and was further handicapped throughout the campaign by a shortage of technicians and litter bearers as well as by cold, rainy weather and difficult mountainous terrain. Although ill, he refused to rest and continued to render invaluable service to his organization in the treatment and evacuation of many casualties. His accomplishments of difficult tasks was the result of his skill, initiative and devotion to duty." Dr. Daly was previously awarded the Purple Heart for wounds received in September 1943 during action at Salerno. He has been overseas since October 1942 and took part in the North African campaign as well as the Italian fighting. Dr. Daly graduated from Wayne University College of Medicine, Detroit, in 1942 and entered the service on July 1 of that year.

MISCELLANEOUS

THE RED CROSS HOME NURSING PROGRAM

Through its home nursing classes the Red Cross is attempting to develop self reliance in the homemaker in handling simple illnesses in the home and in understanding the need for expert medical and nursing assistance in cases of a more serious nature. The homemaker who has had only simple training in home nursing can help the doctor by learning to recognize early symptoms of illness, by observing and by recording for his information such details as the elevation of temperature, the appearance of a skin rash or the presence and intensity of pain. She learns to carry out his orders intelligently, how to keep the patient comfortable and clean, how to fill a hot water bottle and how to use it, how to give an enema, apply a compress, prepare a special diet and carry out communicable disease technic without time consuming questions. She learns to use the telephone intelligently, to report information clearly and calmly, to call as early in the day as possible so he can arrange his schedule of calls.

The Home Nursing course differs from the Volunteer Nurse's Aide course, which is designed to prepare women to assist professional nurses in caring for illness in hospitals, clinics and dispensaries. The course also should be distinguished from courses for "practical" nurses whose services are on a paid basis.

The standard Red Cross Home Nursing course is primarily a homemaker's course in simple nursing skills—intelligent home-making applied to the care of the sick in the home and to family health. It gives information about a safe home environment, including the necessity for a pure and efficient water supply, safe milk and food, screening, ventilation and waste disposal. It inculcates an interest in the general public health and its inevitable relationship to the health of the home. It awakens responsibility for supporting the health officer in his efforts to safeguard the community.

The course is taught, usually on a volunteer basis, by nurses who meet Red Cross qualifications in both professional and

general education. Although based on the Red Cross Home Nursing textbook, the content of the standard course is flexible and easily adapted to various age groups and their needs. The four types of courses designed for men, women and school age young people are:

First, the standard course, which requires not less than twenty-four hours for adult community groups. It includes the various phases of home nursing care. Second, a new streamlined course titled "Six Lessons in Care of the Sick," requiring twelve hours. It is designed for very busy, hard to reach adult groups and covers only the basic procedures in home nursing. Only instructors who have been authorized through a special training course may teach the Six Lessons. Third, the School course, for high school students. This may be given to school or out of school groups. Fourth, a College Course in Home Nursing and Family Health, now in preparation. It is intended for college students or others prepared to work on the college level.

Nurse-instructors spend approximately half of the class time on demonstrations and on supervising the practice of simple procedures, the other half on class discussions of problems. A small certificate, in recognition of the satisfactory completion of the course, is given. This does not imply that the holder is qualified to work for pay outside her home. However, in cases of emergency, or when the home nurse has time for volunteer service, she may assist community health agencies that need her and that are able to provide additional instruction and supervision.

The Red Cross Home Nursing textbook is the basic text for all adult courses and also serves as a permanent reference book in the home. The School Edition is used for the school course. The book has been translated into Spanish for the use of Spanish speaking people both in this country and in Latin America.

Home Nursing is one of the oldest programs of the American Red Cross. In 1908, three years after the Red Cross was chartered by Congress, the idea was originated for this plan of health education for the homes of the country. The program

has gathered impetus with the years. Particularly during the period of war and rehabilitation it is important because of the continued decrease in medical facilities available to civilians. The large number of wounded and disabled men being returned to this country will continue to make the problem acute. In addition, the mass grouping of people, the shifting of large populations because of employment reasons, may lead to an increase of communicable disease and to epidemics that will require the assistance of a citizenry trained in simple skills in caring for the sick in the home.

The Red Cross Home Nursing program is aiming to reach 3,000,000 persons estimated as the minimum additional number who should be trained in these simple skills. That figure has been based on a careful study of the estimated number who may be ill at given times in the homes of America. It has been found that it is usually women between the ages of 15 and 59 who normally care for the sick at home. Excluding those who already have been trained in home nursing, as nurse's aides or as professional nurses, it is estimated that the number still needed to insure safe nursing care would be at least 3,000,000.

How can the doctor help the Red Cross to reach the right persons? By asking who in his patient's family has had a home nursing course and by expressing appreciation to those who have demonstrated the value of the course; by directing prospective students to the Red Cross chapter for information about classes; by urging professional nurses—including housewives and others inactive in nursing—to arrange time for teaching classes (26,000 nurses are needed this year as instructors); by participating in the institutes for nurse-instructors and making recordings for local radio programs; by discussing home nursing at medical meetings, perhaps inviting a Red Cross Home Nursing committee member to explain the program; by speaking at closing class exercises (educational films on immunization or other appropriate subjects may be shown at such times); displaying the textbook, posters and dodgers on Red Cross Home Nursing in his office and including a dodger or statement on home nursing with his bills; urging the support of classes by various women's auxiliaries and other groups interested in health; calling attention to the Red Cross Nursing textbook as a valuable guide for the homemaker, even though she may not be able to attend the home nursing class.

The Red Cross is eager to help overworked doctors and professional nurses in these trying times by providing understanding people in the homes where sickness strikes. It asks the help of the medical profession in making a success of its home nursing program.

ARMY PSYCHIATRIST ASKS COOPERATION OF INDUSTRY

Lieut. Col. Malcolm J. Farrell, deputy director of the Neuropsychiatry Consultants Division of the Office of the Surgeon General, in speaking before the industrial relations conference of the American Management Association in New York City recently, stressed the need for industry to give employment whenever practicable to men disqualified for military service for psychiatric reasons. Dr. Farrell deplored the popular misunderstanding of psychiatric conditions and especially confusion over the meaning of the term psychoneurosis. Up to 80 per cent of the men who have become psychiatric casualties in combat, he said, have been cured when their cases were properly recognized and treated. Many others who cannot continue to perform some type of army duty and those who have been eliminated early in their training periods are capable of performing useful work as civilians.

FIRST NURSES TO SCHOOL OF MILITARY GOVERNMENT

Capt. Grace Alt, Fort Meade, Md., and Capt. Mildred Lueka, McCloskey General Hospital, Texas, both of the American Nurse Corps, have been selected as the first nurses to attend the School of Military Government at Charlottesville, Va., to qualify for assignment to the Civil Affairs Administration in the Far East.

MUSTERING-OUT PAYMENTS OF DISCHARGED ASTP STUDENTS

In reply to an inquiry concerning the discharge of premedical and medical students, the following was received from the Office of the Fiscal Director, September 21: "ASTP premedical and medical students, also premedical and dental students, are not to be regarded as discharged because of importance to the national health safety or interest so as to preclude payment of mustering-out payment where otherwise qualified."

CIVILIAN INSECT CONTROL PROGRAMS AFTER WAR

At the end of the war the United States will be in an extremely favorable position to wage a major campaign against disease-carrying insects as a result of the tremendous effort the Army has made to defeat them in combat areas throughout the world. Efficient methods of insect control have been worked out and thousands of men have been trained in the techniques developed. The men and the methods will be available for mosquito and other insect control programs, once peace and victory are achieved. They will make possible renewal of civilian efforts to eliminate the nuisance of the mosquito and at the same time guard against the diseases the mosquito is known to transmit, such as malaria, dengue and yellow fever and perhaps encephalitis. The Army also developed new insect repellants, effective not only against mosquitoes but also against mites, fleas and other insects known to be disease carriers.

Among the new weapons to be available to civilians after the war will be DDT, the new chemical insect killer, with which the Army solved the problem of typhus in Italy by destroying the body louse which transmit the infection. DDT is used in the Army in heavy oil solution for spraying on water or in light oil solution for spraying on walls and furniture. It is as effective against mosquitoes as it is against lice.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Mayo General Hospital, Galesburg, Ill.: Laboratory Diagnosis and Its Relationship to Treatment, Drs. William S. Hoffman and Steven O. Schwartz, November 1.

Camp Ellis, Camp Ellis, Illinois: Symposium on Organic Neurology, Drs. Francis J. Gerty and Loren William Avery, November 1.

Chanute Field, Rantoul, Ill.: Chronic Chest Diseases and Diseases of the Larynx, Drs. Paul H. Holinger and Henry C. Sweany, November 1.

Schick General Hospital, Clinton, Iowa: Medical Rehabilitation, Dr. Frank H. Krusen, October 27.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, October 14, p. 440)

COLORADO

Colorado General Hospital, Denver. Capacity, 270; admissions, 3,718. Dr. Maurice H. Rees, Medical Superintendent (intern).

IOWA

Mercy Hospital, Des Moines. Capacity, 193; admissions, 5,357. Sister M. Anita, Superintendent (interns, residents).

NEW YORK

St. John's Long Island City Hospital, Long Island City. Capacity 284; admissions, 5,418. Sister Thomas Francis, Superintendent (interns).

WEST VIRGINIA

St. Mary's Hospital, Clarksburg. Capacity, 192; admissions, 4,201. Sister M. de Sales, Administrator (2 residents—mixed service).

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

Oct. 16, 1944.

Action to Limit Production of Opium

The Department of State reveals that U. S. government missions abroad have been instructed to urge on governments of the chief opium producing countries that steps be taken to limit opium growth and production. While this action is motivated from the point of view of international well-being, the presence of American troops throughout the world makes the control problem a matter of concern in many American homes. The official move by the government was taken following passage by Congress early this summer of a resolution by Representative Walter H. Judd (Republican, Minnesota), long time Far East medical missionary, which called on the President to ask action to limit production to medicinal and scientific requirements "in the interest of protecting American citizens and those of our allies and of freeing the world of an age old evil." U. S. missions will transmit a copy of the Judd resolution to Afghanistan, China, Great Britain (for India and Burma), Iran, Russia, Turkey and Yugoslavia. So far Yugoslavia is the only country to receive the communication.

It is revealed here that United States ships carrying lend-lease goods for Russia and manned by American seamen are

touching port every day in Iran, largest producer, where 50 to 75 per cent of the police force is said to be addicted to the drug habit. Many American and United Nations citizens are in Iran, and American soldiers are also in India and Burma, large producers of opium.

The United States is thus assuming leadership in opium control for the second time, having called the first international commission in 1909. The Judd resolution is described as the first step in present plans. The nation can exert pressure at this time on opium producing countries which are dependent on the United States for money, materials and men. National economies, once dependent on opium production in some instances, are now looking to lend-lease for materials and money in development of railways, highways and factories.

Representative Judd points out that when he proposed his resolution the opium revenue in British, Dutch and French Far East possessions ranged from 2 per cent of income in the Dutch East Indies up to 20 per cent in the British Straits Settlement colony, including the island of Singapore. A hopeful development in the situation is the promise that was made by the British and Netherlands governments in November 1943 to prohibit the use of opium for smoking and to abolish opium monopolies in Far East territories when the Japs have been removed.

MEDICAL ECONOMIC ABSTRACTS

PROGRESS OF MEDICAL SERVICE PLANS

To form a basis for mutual comparison, the various medical society prepayment plans were asked by the Bureau of Medical Economics for as recent a financial report as it was possible to give. Some of the principal items of the reports received are given here. Copies of these reports in full are available for administrators of all existing and proposed plans.

Colorado Medical Service, Inc.—This was organized May 1, 1942 to serve metropolitan Denver and offers only a surgical contract. On March 1, 1943 it had about 5,000 members. On Sept. 30, 1943 it had received \$17,856.20 income from subscribers and had an operating expense of \$16,568.75. Its balance showed a surplus of \$10,914.72.

Dallas County Medical Plan.—This was organized in 1940 to serve Dallas County and offers both medical and surgical contracts. On Jan. 1, 1944 it had 167 medical contracts and 24 surgical contracts. Its income was \$6,951.25 and its total expense \$4,960.23, leaving a net gain of \$1,991.02. It had resources of \$9,713.98 and a surplus of \$1,991.02.

Group Hospital Service, Inc.—This was organized in 1943 as a plan for medical care sponsored by Group Hospital Service and serves the state of Delaware. It offers its contracts only in the form of a surgical service rider, issued only to subscribers to a hospital service plan. On Dec. 31, 1943 it had a total of 4,622 males and 6,166 females, including subscribers and dependents. On Dec. 31, 1943 it had received as income from subscribers \$25,011.45, expended \$8,700.52 and has a reserve of \$16,310.93.

Hospital Saving Association of North Carolina, Inc.—This is a combination hospitalization and surgical plan, and the financial figures cover the combined operation. The hospitalization contract covers 66,162 males and 90,886 females. The surgical plan covers 13,535 males and 16,638 females. The total income from all subscribers for the period from Dec. 31, 1943 was \$932,587.38. The plan as a whole now has a surplus of \$311,703.30.

Massachusetts Medical Service.—The plan was organized in July 1942 and serves the state of Massachusetts. It offers a contract covering surgery, obstetrics, x-ray and anesthesia. On Dec. 31, 1943 it had a membership of 9,678 males and 11,306 females. During 1943 it received an income from subscribers of \$41,949.78, of which it expended \$12,045.36. On March 29, 1944 it had a surplus of \$37,045.36.

Medical Service Association, Inc.—This was organized in 1940 and serves fourteen counties in North Carolina. It is operated only jointly with the local hospital service plan, with the medical contract on an indemnity plan. The membership of Oct. 30, 1943 was 13,031. Income to April 18, 1944 was \$53,317.16. Of this amount \$45,734.39 was spent for medical services and \$4,775.96 for operating expense; \$2,244.69 remains in the treasury. There is an operating reserve of \$562.12.

Medical and Surgical Care, Inc.—This was organized in 1941. The original plan was changed somewhat in May 1942. It serves fifteen counties in central and northern New York. It offers its surgical contract with a medical rider operative only after the first two calls of any illness and allows credits on the patient's bill. About 19,200 persons are now enrolled for the ten months ended Oct. 31, 1943. There was a total income of \$111,851.14; disbursements amounted to \$94,906.09, and the plan has a surplus of \$15,320.71.

Michigan Medical Service.—The first contract was issued March 15, 1940. The plan serves the state of Michigan, and at present its contracts are entirely surgical. On Dec. 31, 1943 it had a total of 467,717 subscribers and dependents. Its income during 1943 was 3,367,372.95. During that year the total disbursements were \$3,063,837.62, showing a total gain of \$303,535.33. It has now accumulated a reserve of \$136,242.71.

Western New York Medical Plan, Inc.—This was organized in March 1940 to serve six counties in western New York and offers medical-surgical contracts. It has 7,602 male and 7,437 female medical-surgical contracts, and 2,339 male and 2,711 for female surgery only. Its total income up to Dec. 31, 1943 was \$119,275.93. Of this it expended \$103,796.96 and has accumulated a surplus of \$8,286.88.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Dr. Jacob C. Geiger, San Francisco, on October 14 received the honorary degree of doctor of science from Tulane University of Louisiana School of Medicine, New Orleans. Dr. Geiger gave the commencement address on this occasion. Dr. David E. Smallhorst, Glendale, health officer for the San Fernando District, has retired under civil service rules. He has been connected with the Los Angeles County Health Department since 1926.

Court Orders Restoration of Physician's License.—The state district court recently upheld a superior court verdict ordering restoration by the state board of medical examiners of the license of Dr. Thomas D. Wyatt, Redding, newspapers reported August 10. The license had been revoked by the board when it charged Dr. Wyatt with performing two illegal operations at a Redding hospital in March 1942, it was stated (THE JOURNAL, June 26, 1943, p. 629). The women involved testified in superior court that the operations were legal.

Position Open in San Diego.—The department of civil service and personnel of the County of San Diego announces a vacancy in the position of assistant director of public health of San Diego County. Applicants must be citizens of the United States, have a license to practice medicine in the state, have two years of successful experience in a recognized department of public health and present a certificate or degree from a recognized school of public health. The salary is between \$405 and \$422 a month. Additional information may be obtained from Room 212, Civic Center Building, San Diego 1.

GEORGIA

Personal.—Dr. Jolin P. Kennedy recently retired as health officer of Atlanta, a position he held for forty-three years.

New Professor of Pediatrics.—Dr. Roger W. Dickson was recently appointed professor and chairman of the department of pediatrics at Emory University School of Medicine, Atlanta. Dr. Dickson was also made chief of the pediatric service in the Grady Hospital, Atlanta.

Building Planned for Georgia Medical School.—A new building to cost approximately \$200,000 will be constructed for the University of Georgia School of Medicine, Augusta, when the war is over to take the place of the old college building, according to Dr. G. Lombard Kelly, dean. The old building will be converted into a student union, housing a swimming pool, gymnasium, restaurant and recreation rooms.

INDIANA

Changes in Health Personnel.—Dr. Clarke Rogers, Indianapolis, has been appointed a member of the Indianapolis Board of Health to succeed Dr. Arthur F. Weyerbacher, resigned. Dr. Stephen C. Bradley has been placed in charge of the department of contagious diseases of the Terre Haute board of health, succeeding the late Dr. Maurice B. Van Cleave.

Dr. Page Goes to Cleveland Clinic.—Dr. Irvine H. Page, for seven years director of the Eli Lilly Laboratory for Clinical Research and the Lilly Clinic, Indianapolis, has resigned to become director of research for the Cleveland Clinic, Cleveland, effective January 1. Dr. Kenneth G. Kohlstaedt, assistant superintendent of the Indianapolis City Hospital, will succeed Dr. Page.

IOWA

First Annual Meeting on Mental Hygiene.—The Iowa State Society for Mental Hygiene, which was organized during the past year with Dr. Walter L. Bierring, Des Moines, state health officer, as president, will hold its first annual session at the Hotel Kirkwood, Des Moines, October 28. Among the speakers will be Major S. O. Meisner on "Problem of the Constitutional Psychopath"; Luther E. Woodward, Ph.D., New York, "Social Adjustment of Returning Veterans," and Mr. Everett S. Elwood, president, American Occupational Therapy

Association, Philadelphia, "Occupational Therapy in War and Postwar." A panel discussion on "Mental Hygiene: Postwar will be conducted by Ralph H. Ojemann, Ph.D., Iowa City; Dr. Andrew H. Woods, Iowa City; King Palmer, Iowa Board of Social Welfare, Des Moines; Marjorie O. Lyford, R. N., Des Moines, and Dr. Robert L. Jackson, Iowa City.

KENTUCKY

Changes in Health Personnel.—Dr. Don E. Wilder, Grayson, has been named health officer of Breathitt County. Dr. Wallace Byrd, Williamstown, has resigned as health officer of Grant County. Dr. William L. Wright, Louisville, has been placed in charge of the Bell County Health Department, Pineville. Dr. Charles J. Grubin, Arlington, Va., has been named health officer of Madison County with offices in Richmond.

State Medical Election.—Dr. J. Watts Stovall, Grayson, was chosen president-elect of the Kentucky State Medical Association at its annual meeting in Lexington and Dr. Oscar O. Miller, Louisville, was inducted into the presidency. Other officers include Drs. Kirby S. McBee, Owenton, Clement V. Hiestand, Campbellsville, and Walter I. Hume, Louisville, vice presidents. Dr. Philip E. Blackerby, Louisville, state health officer, is the secretary. The next annual meeting will be held in Bowling Green.

Visiting Professors Provided Under New Fund.—The Commonwealth Fund has established a fund to bring visiting professors to the University of Louisville School of Medicine. Dr. Carl V. Moore, associate professor of medicine, Washington University School of Medicine, St. Louis, was to start his residence October 9 to continue through October 21, and Dr. William F. Windle, professor of neurology and director of the institute of neurology, Northwestern University Medical School, Chicago, will be in residence for the month of November. Changes in the faculty at Louisville include the resignation, effective November 15, of Dr. Gerhard Lehmann, associate professor of pharmacology, to become pharmacologist of Hoffmann-La Roche, Inc., Nutley, N. J. Dr. Richard C. Porter, instructor in medicine, University of Buffalo School of Medicine, and associate director of laboratories in the Edward J. Meyer Memorial Hospital, Buffalo, has been made assistant professor of pharmacology at Louisville. He has a medical service in the Louisville General Hospital and will teach applied pharmacology to the medical students.

LOUISIANA

New Tuberculosis Society.—A charter has been adopted and the organization completed of the Tuberculosis Association of New Orleans with Drs. John H. Musser as president and Julius L. Wilson as medical consultant. The group formerly functioned as the Tuberculosis Committee of New Orleans.

Personal.—Dr. Marie-Louise M. Pareti has resigned as acting chief of the section of maternal and child health of the Louisiana State Board of Health to become assistant to Dr. James R. Reinberger, Memphis, Tenn. Dr. Elvira A. Corrales-Smith, Monro, has been appointed director of the Acadia Parish Health Unit.

MICHIGAN

Bruce Testimonial Lecture.—Dr. John W. Hirshfeld, Detroit, will deliver the opening lecture in each of the nine centers sponsored by the committee on postgraduate medical education of the Michigan State Medical Society this fall. His subject will be "Penicillin" and the lecture has been designated the James D. Bruce testimonial lecture in honor of Dr. Bruce, who has been chairman of the committee on postgraduate medical education for a long period.

Beaumont Gavel Given to State Society.—At special ceremonies recently the Mackinac Island State Park Commission, Mackinac Island, presented the Beaumont gavel to the Council of the Michigan State Medical Society. The gavel was carved out of the only piece of timber which has ever been allowed to be taken from the Early House on Mackinac Island, where Dr. William Beaumont cared for Alexis St. Martin. The wood is pure white pine and was grown and cut on the island and used in the original structure of the Early House. The presentation was made by Wilfred F. Doyle, chairman and resident commissioner of the Mackinac Island State Park Commission, who reported that the Early House had been purchased through a grant made by Parke, Davis & Company and outlined the plans to put the building into shape as a museum and memorial to Dr. Beaumont. Mr. Doyle recom-

recommended the appointment of a permanent committee representing the Michigan State Medical Society, the Beaumont Foundation and the Mackinac Island State Park Commission to ensure maintenance of the Beaumont shrine.

Nutrition and Public Health.—"Implications of Nutrition and Public Health in the Postwar Period" will be the theme of a conference November 3 in the auditorium of the Horace Rackham Memorial Building, Detroit, under the auspices of the Children's Fund of Michigan. The following will participate:

- Dr. Frank G. Boudreau, New York, The International Implications of Freedom from Want of Food.
- Dr. Paul R. Cannon, Chicago, The Importance of Proteins in Resistance to Infection.
- Dr. L. Emmett Holt Jr., Baltimore, Protein Deficiencies in Man.
- Dr. Philip C. Jeans, Iowa City, Maintaining Dental Health.
- Charles G. King, Ph.D., New York, Vitamins and the Health of the Nation.
- Leonard A. Maynard, Ph.D., New York, Food Production for Better Health and Longer Life.
- Elmer V. McCollum, Sc.D., Baltimore, Our National Diet and Future Health.
- Roy C. Newton, Ph.D., Chicago, Role of Food Technology in Improving Nutrition.
- Dr. Harold C. Stuart, Boston, Nutritional Reconditioning of Children in Occupied Countries.
- Group Captain Frederick F. Tisdall, R. C. A. F., Research and Nutrition for Human Health.

MINNESOTA

Proposed Medical Foundation.—The merger of two funds within the Hennepin County Medical Society has been proposed to found the Hennepin County Medical Foundation. This plan, which would combine an existing trust fund in the society and the recently approved annuity-insurance setup, would finance medical research and laboratory projects, lectures, medical scholarships, awards for medical achievements, a medical library, the promotion of health education and loans, without interest, to physicians who have served in the armed forces and who will be in need of assistance in reestablishing themselves. It is believed that the contributions to the existing trust fund or to the proposed new fund would increase if contributions could be considered tax exempt, and a ruling on the subject is now under consideration.

NEW JERSEY

Dr. Shangle Honored.—A dinner was held in Elizabeth recently in honor of Dr. Milton A. Shangle in recognition of his promotion to the position of senior attending surgeon at the Elizabeth General Hospital and Dispensary, where he has served successively as intern, dispensary physician, assistant surgeon, gynecologist, obstetrician and surgeon. A portrait of Dr. Shangle, executed by Maxwell Stewart Simpson, Elizabeth, was presented to the physician by members of the staff. Dr. Shangle graduated at the Columbia University College of Physicians and Surgeons in 1900 and came to Elizabeth the following year.

Industrial Health Study.—Dr. Marie A. Scna, Newark, has been engaged by the bureau of industrial health of the New Jersey Department of Health to conduct a study of industrial health of workers in the food processing and related agricultural industries. Information on the medical facilities and plant health programs of canneries and of fertilizer, flour, feed and other industries will be obtained. The health and sanitary facilities of workers will be observed, according to *Industrial Medicine*. The bureau is beginning the publication of an Industrial Health Bulletin, the first issue of which will be devoted to the prevention of heat illness.

NEW YORK

New Executive Secretary of Westchester County.—Mr. Boyden Roseberry, director of the medical department of the Children's Aid Society of New York, is the new executive secretary of the Medical Society of the County of Westchester.

Ninety Years of Age.—Dr. Myron E. Carner, who has been active in Lyons fifty-six years, celebrated his ninetieth birthday, September 17. The physician graduated at the University of Vermont College of Medicine, Burlington, in 1885.

Graduate Lectures.—Morton C. Kahn, Ph.D., associate professor of public health and preventive medicine, Cornell University Medical College, New York, will address the Memorial Hospital of Greene County and the Greene County Medical Society, October 26, Catskill, on "Transmission of Disease by Lice, Fleas, Ticks and Other Insects." On November 17 Dr. Leo E. Gibson, professor of clinical surgery (urology), Syracuse University College of Medicine, Syracuse, will

discuss "Infections of the Genitourinary Tract" before the Cortland County Medical Society. Dr. Albert G. Swift, professor emeritus of surgery, Syracuse University College of Medicine, addressed the society, October 20, on "Surgical Lesions of the Biliary Tract."

New York City

Medical Alumni Honors Doorman.—Charles Costello, 75 year old doorman at Columbia University College of Physicians and Surgeons, was the guest of honor at a dinner, September 26, given by the medical school alumni association in recognition of his completion of fifty years of service to the university. Guest speakers at the dinner, which was the annual fall meeting and dinner of the alumni association, included Comdr. Gordon M. Bruce (MC), John F. Kieran and Dr. Willard C. Rappleye, dean of the college. Dr. John J. H. Keating, president of the alumni association, presided.

First Achievement Award Goes to Robert Dickinson.—On September 28 Dr. Robert L. Dickinson, in charge of a studio of medical art at the New York Academy of Medicine, received the first Alumni Achievement Award at the commencement exercises of Long Island College of Medicine, Brooklyn. Dr. Dickinson graduated at the college in the class of 1882. The medallion which constitutes the award bears the head of Hygeia, goddess of health. It has been established to honor graduates of the college who have made notable contributions to American medicine. Eleven prize awards went to ten students in the graduating class who trained for the army medical corps and one who trained for the navy medical corps. Top honors in the class went to Lieut. Hector Wright Benoit Jr., M. C., who received the Mitchell prize, awarded to the member of the class who in the judgment of the faculty is best qualified in all departments of medicine, and Lieut. Leonard Lincoln Madison, M. C., who received the Phi Delta Epsilon prize, awarded for the highest scholastic record. Lieutenant Benoit, who graduated at Cornell University, is serving his internship at Kings County Hospital and Lieutenant Madison, who graduated at Ohio State University, is serving his internship at Mount Sinai Hospital. Nine other prizes include:

- Lieut. Raymond Saigh, M.C., the Dudley Medal for the best clinical report of a case in the medical wards of the college.
- Lieut. Grafton Edgar Burke, M. C., the Dudley Memorial Medal for the best clinical report of a case in the surgical wards of the college.
- Lieut. John Andrew Matheson, M. C., the Ford Prize for the best dissertation.
- Lieut. Charles Mindell Plotz, M. C., the Nathan H. and Johanna Szerlip Medal for the best thesis on pneumonia.
- Lieut. Leonard Castleman, M. C., the Alumni Prize to the member best qualified in gynecology.
- Lieut. Joseph Daniel Casolaro, M. C., Prize of the Class of 1898 to the member whose scholastic average in the fourth year has shown the greatest improvement over that of previous years.
- Lieut. Joseph John Lambert Jr. (MC), the Obstetric Prize for the best thesis on a subject in obstetrics.
- Lieut. Bernard Anatole Sachs, M. C., the Robert R. Benedict Jr. Prize for the best report on a psychosomatic study.
- Lieut. Herbert Jay Rosen, M. C., the Joseph Howard Raymond Prize in physiology.

NORTH CAROLINA

Officers of Examining Board.—Dr. Charles W. Armstrong, Salisbury, was chosen president of the North Carolina State Board of Medical Examiners at the board's semiannual meeting in Raleigh in September, succeeding Dr. Lester A. Crowell Jr., Lincolnton. Dr. Ivan M. Proctor, Raleigh, is the new secretary of the board, succeeding Dr. William D. James, Hamlet.

Dr. Roger Baker Goes to Alabama.—Dr. Roger D. Baker, associate professor of pathology in charge of surgical pathology, Duke University School of Medicine, Durham, has been appointed professor and chairman of the department of pathology in the Medical College of Alabama at Birmingham, effective on December 1. Dr. Baker requests that necropsy and surgical materials for the Fungus Disease Registry be sent to him at Birmingham 5 after that date. The mycologic and serologic materials of this registry should continue to be sent to the office of Dr. David T. Smith, Duke Hospital, Durham.

Personal.—Dr. Yates S. Palmer, Valdesco, has been appointed a member of the North Carolina Hospitals Board of Control.—Dr. Harold C. Whims, Newton, health officer of Catawba County, has also been given the administrative direction of the unit in Iredell County.—James C. Andrews, Ph.D., professor of biologic chemistry and head of the department at the University of North Carolina School of Medicine, Chapel Hill, is serving as exchange professor of biologic chem-

istry and nutrition at the National University of Guatemala Medical School, Guatemala City, for a period from September 1 to January 1. Granvil C. Kyker, Ph.D., is acting head of the department at the university.

OREGON

State Medical Election.—Dr. Lansford M. Spalding, Astoria, was chosen president-elect of the Oregon State Medical Society at its meeting in Portland, September 3, and Dr. Edward H. McLean, Oregon City, was installed as president. Other officers include Drs. James C. Hayes, Medford, Dean P. Crowell, Marshfield, and Burton A. Myers, Salem, vice presidents. Dr. Thomas S. Saunders Jr., Portland, was named secretary and Dr. Richard Lloyd Tgart, Portland, treasurer. Portland was tentatively chosen as the place for the 1945 session sometime in September.

PENNSYLVANIA

State Medical Election.—Dr. William L. Estes Jr., Bethlehem, was named president-elect of the Medical Society of the State of Pennsylvania at its annual meeting, September 20, and Dr. William Bates, Philadelphia, was inducted into the presidency. Dr. Walter F. Donaldson, Pittsburgh, is secretary. The next annual session will be held in Philadelphia about October 1.

Philadelphia

Lectures on Mental Hygiene.—The committee on nervous diseases and mental hygiene of the Philadelphia County Medical Society opened a series of lectures on mental hygiene September 25 with a talk by Dr. Frederick H. Allen on "Mental Health from the Standpoint of Child Guidance" and one by Dr. Ralph M. Tyson on "The Relation of Mental Health to the Growth and Development of the Child." Others in the series include:

- Drs. Edward Weiss, Mental Health as Related to Internal Medicine, and O. Spurgeon English, Psychosomatic Medicine, October 2.
- Drs. Winifred B. Stewart, Delinquency in Minors as Seen at the Municipal Court, and Gerald H. J. Pearson, Disturbances of Mental Health as Recognized in the Delinquency of Minors, October 9.
- Drs. Edward A. Steinhilber, Recognition of Disturbances of Mental Health, and Joseph C. Yaskin, Aids to the General Practitioner in the Handling of Psychoneurosis, October 16.
- Dr. Bernard J. Alpers, Disturbed Mental Health from Head Injuries and as an Organizational Condition, and Lieut. Comdr. Joseph F. Hughes (MC), The Study of Psychoses, October 23.
- Drs. Leroy M. ... of Psychoneurotic Service Men and Their Psychologic Adjustment to Civilian Life, and Robert A. Matthews, Marital Situations in Which Mental Health Plays a Part, October 30.
- Drs. H. Craig Bell, Responsibility of the Medical Man in the Role of an Activator of Mental Disturbance, and Samuel B. Hadden, Treatment of Psychoses, November 6.

Care of Mentally Defective Children.—A committee appointed by Charles L. Brown, president judge of the Municipal Court of Philadelphia, to study the problem of the care and disposition of the feeble-minded, epileptic and the defective delinquent, has submitted a report. The committee has divided its recommendations into two groups, those concerned with institutional placement and those with extrainstitutional family placement. Concerning the former, it is urged that immediate provision should be made for an increase of at least 50 per cent in the bed capacity to be used largely for defective children of low earning and indigent families. For a long term program the bed capacity must be increased by at least 100 per cent. Specific recommendations pertain to certain institutions, one suggestion urging the establishment of a new institution for the feeble-minded outside of Philadelphia to serve the city and the surrounding counties, thereby with other additions helping to eliminate the disparity (estimated as 2 to 1) between the bed capacity for defectives in the western part of the state as compared with the eastern part of the state. The report emphasizes the immediate need for special provisions to care for the group requiring custodial care (about 800 low grade defectives for Philadelphia). Special accommodations should be made for cases with accompanying physical handicaps. It is pointed out that an institution for defective delinquent boys, both white and Negro, under the age of 15 years is urgently needed. This should be an institution of the cottage system type with provisions for manual training through trade and farm schooling. It should be state controlled and, with a capacity of about 200, should serve Philadelphia and adjacent counties. Added accommodations are needed for a similar group to meet the needs of boys 16 and 17 years of age who are now committed to the Huntingdon Reformatory. There is also a need for an institution for female defective delinquents, irrespective of age and color, and

one for the more seriously delinquent girls below 16 years of age. In its consideration of family placement facilities and extrainstitutional (community) care, the organization of a central agency, board of review, is urged for Philadelphia to register all mental defectives, epileptic persons and defective delinquent cases, to review all problem cases and to maintain follow-up records. This board should be established under the Philadelphia Department of Public Welfare and have available all data concerning changes in status and location of individual children. The expansion of the release and parole policy of institutions is treated in the report and the urgent need for special consideration in the family care in foster homes. Individual recommendations are made covering the systematic training, investigation and selection of the foster family.

TENNESSEE

Changes in Health Officers.—Dr. Joseph T. Nardo, Somerville, has resigned as director of the Fayette County Department of Health to reenter the U. S. Public Health Service.—Dr. Rutherford O. Ingham, Johnson City, has resigned as director of the Washington County Health Department. He will be succeeded by Dr. Marion G. Fisher, Jonesboro.—Dr. Robert B. Griffin has been named director of the Jackson and Madison County Health Department to succeed Dr. Lamar A. Byers, who accepted a similar position in Coos County, Oregon.—Dr. Fray O. Pearson, director of the Chattanooga-Hamilton County Health Department, has resigned to enter private practice and become associated with the Earl Campbell Clinic, effective October 1. Dr. Paul M. Golley, director of the division of tuberculosis control, has been named director of the health unit. Dr. Pearson became head of the Hamilton County unit in 1939 and remained in the position when the city and county health departments were merged in 1941.

UTAH

Personal.—Dr. Ezra C. Rich, Ogden, was given a dinner by the Weber County Medical Society, August 23, in recognition of his completion of fifty years in the practice of medicine and of his eightieth birthday.

University News.—Dr. James P. Kerby has resigned as associate clinical professor of medicine (radiology) at the University of Utah School of Medicine, Salt Lake City. He had been serving on a part time basis. On September 10 the first graduation exercises of the new four year medical school were held. Thirty-two men and three women were granted the degree of doctor of medicine. Honorary degrees of doctor of science were conferred on Thomas Parran, Surgeon General of the U. S. Public Health Service, who gave the commencement address, and Dr. Samuel C. Baldwin, one of the pioneer orthopedic surgeons in Utah.

WISCONSIN

State Medical Election.—Dr. Patrick R. Minahan, Green Bay, was named president-elect of the State Medical Society of Wisconsin at its annual meeting in Milwaukee, September 19. Dr. Charles Fidler, Milwaukee, was installed as president. Mr. Charles H. Crownhart, Madison, is the secretary.

Meeting of Chest Physicians.—On September 17 the first annual meeting of the Wisconsin Chapter of the American College of Chest Physicians was held at the Hotel Schroeder, Milwaukee. The speakers included:

- Dr. Frederick M. F. Meixner, Peoria, Ill., Pregnancy in Tuberculosis.
- Dr. Minas Joannides, Chicago, Tuberculosis Control in General Hospitals.
- Drs. Abraham R. Hollender and Paul B. Szanto, Chicago, Tuberculosis of the Nasopharynx.
- Dr. Richard M. Davison, Chicago, Surgical Management of Empyema.
- Dr. Jay Arthur Myers, Minneapolis, The Medical Profession and the Control of Tuberculosis.

Dr. Leon H. Hirsh, West Allis, is secretary-treasurer of the Wisconsin chapter.

University Society Meetings.—The University of Wisconsin Medical Society, Madison, opened its regular meetings October 3 with a presentation by Merle S. Nichols, Ph.D., and Paul H. Phillips, Ph.D., on "Fluorine and Dental Caries." Subsequent lectures in the series will include:

- Dr. Charles J. Thill, Present Status of Penicillin Therapy, November 7.
- Staff of McArdle Memorial Laboratory, Current Research Problems in Cancer, December 5.
- Malcolm R. Irwin, Ph.D., Genetics and Resistance to Disease, January 2.
- John A. E. Eyster, Ph.D., Recent Advance in Cardiac Physiology, February 6.
- Harland W. Mossman, Ph.D., and Roland K. Meyer, Ph.D., Some Special Structures and Functions of the Ovary, March 6.
- Dr. Philip P. Cohen, Some Aspects of Protein Metabolism in Disease, April 3.
- Dr. Raymond C. Herrin, Recent Advance in Kidney Physiology, May 1.

GENERAL

National Committee on Alcohol Organized.—The organization of a National Committee for Education on Alcoholism, Inc., was announced October 2. Offices will be at 2 East 103d Street, New York. Elvin M. Jellinek, Sc.D., director of the Yale School of Alcohol Studies, New Haven, Conn. (*THE JOURNAL*, June 12, 1943, p. 454), is chairman of the board of the new committee and Mrs. Marty Mann is executive director.

Achievement Award Goes to Florence Seibert.—The National Achievement Award medal, sponsored by Chi Omega Sorority annually to honor "an American woman of notable accomplishments," was presented to Florence B. Seibert, Ph.D., associate professor of biochemistry at the Henry Phipps Institute in Philadelphia, October 6, by Mrs. Roosevelt. The honor goes to Dr. Seibert for her work in tuberculosis research.

Dr. Goodpasture Receives Sedgwick Medal.—The Sedgwick Memorial Medal of the American Public Health Association was presented to Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, October 3. The medal is given for distinguished service in public health. Dr. Goodpasture, among other achievements, is recognized for his work on originating a method to cultivate micro-organisms of typhus fever.

Sage Foundation Creates Department of Studies in the Profession.—Esther Lucile Brown has been appointed director of the newly organized department of studies in the professions of the Russell Sage Foundation, New York. Miss Brown has been a member of the foundation's staff since 1933 and is the author of five volumes dealing respectively with the professions of engineering, law, medicine, nursing and social work. According to an announcement, the department will continue to make studies or carry on research in the social aspects of the professions, having completed five studies before its formal organization.

Special Society Elections.—Major Barnes Woodhall, M. C., was elected president of the American Academy of Neurological Surgery at its recent meeting in White Sulphur Springs, W. Va., Dr. Arthur R. Elvidge, Montreal, vice president and Dr. Theodore C. Erickson, Madison, Wis., secretary-treasurer. —Capt. John C. Adams (Mc) was chosen president-elect of the Aero Medical Association of the United States at its annual meeting in St. Louis, September 4, and Brig. Gen. Eugen I. G. Reinartz, M. C., was installed as president. Other officers include Dr. Delazon S. Bostwick, Ardmore, Pa.; Major Gen. David N. W. Grant, M. C.; Dr. William R. Stovall, Washington, D. C.; Air Commodore James W. Tice, R. C. A. F., and Col. Arnold D. Tuttle, M. C., retired, vice presidents; Dr. James C. Braswell, Tulsa, Okla., business manager and Dr. David S. Brachman, Detroit, secretary-treasurer.

Neuropsychiatric Meeting.—The Central Neuropsychiatric Association will hold its annual meeting at the Palmer House, Chicago, October 31. Among the speakers will be:

Dr. Loren W. Avery, Chicago, The Neurologic Symptoms Associated with Porphyria.

Dr. Abram E. Bennett, Omaha, Meningioma of the Foramen Magnum.

Dr. John L. Garvey, Milwaukee, Cases of Serum Neuritis.

Dr. Ladislav J. Meduna, Chicago, The Common Factors in Shock Therapy.

Dr. Howard D. McIntyre, Cincinnati, The Prognosis and Treatment of Multiple Sclerosis.

Dr. Joseph C. Michael and Charlotte Buhler, Minneapolis, Comparative Diagnostic Studies with the Use of Rorschach, Murray Apperception and Minnesota Multiphasic Tests.

Dr. Richard B. Richter, Chicago, Degeneration of the Basal Ganglia from Chronic Carbon Disulfide Poisoning in Monkeys.

Dr. Andrew L. Skoog, Kansas City, Mo., Nervous Complications of Sickle Cell Anemia.

Dr. Harold C. Voris, Chicago, Massive Extrusion of Lumbar Intervertebral Disks.

Other sessions will be held at the University of Chicago, Northwestern University, University of Illinois and Loyola University medical schools.

Maternal Mortality.—In 1942 there were twenty-nine states in which the maternal death rate was less than 2.5 per thousand live births, a record indicating the continued reduction in maternal mortality, according to statisticians of the Metropolitan Life Insurance Company. Two years earlier only two states recorded such a low figure. Of all the states South Carolina alone in 1942 had a maternal death rate of more than 5 per thousand live births, while the number of states totaled thirty-one in 1936. The change is attributed chiefly to the widespread use of sulfonamide drugs in cases

of puerperal septicemia. In 1942 the leading causes of maternal deaths were septicemia, which accounted for more than 2,800 deaths, puerperal toxemia, which was responsible for 1,900 deaths, and puerperal hemorrhage, which caused about 1,100 deaths. One out of every 6 maternal deaths in the United States is due to abortion. This figure is an understatement, it was stated, "because many of the fatalities from illegal abortion are not reported as such and therefore are classified under other causes."

Committee for Mental Hygiene.—The thirty-fifth annual meeting of the National Committee for Mental Hygiene will be held at the Hotel Pennsylvania, New York, November 8-9. The program has been divided into four sections: mental hygiene of industry and reconversion, rehabilitation and the returning veteran, race relations and services to the mentally ill today. Included among the speakers will be:

Col. H. Edmund Bullis, The Hazards of Industrial Change-Over.

Dr. Bruno Solby, Washington, D. C., The Meaning of Mental Hygiene in Industry.

Dr. Matthew Brody, Brooklyn, Dynamics of Mental Hygiene in Industry.

Features of a luncheon session will be the presentation of the Lasker Award in Mental Hygiene and an address by Lyman Bryson of the Columbia Broadcasting System, New York, on "Effect of Peace Conditions on International Amity."

Government Services

Medical Director of Public Health District
Appointed

Dr. Otis L. Anderson, Washington, has been appointed medical director of district number 4 of the U. S. Public Health Service, with headquarters at New Orleans, to succeed Dr. Charles L. Williams, who recently went to Washington to become director of the Bureau of States Services (*THE JOURNAL*, September 9, p. 117).

Rotating Internships and Residencies

Applications are now being accepted to fill positions as rotating interns and psychiatric residents at St. Elizabeths Hospital, the federal institution for the treatment of mental disorders in Washington, D. C. The positions pay \$2,433 a year, including overtime pay. The internship consists of nine months of rotating service including medicine, surgery, pediatrics (affiliation), obstetrics (affiliation) and, as conditions permit, psychiatry and laboratory. Applicants must be third or fourth year students in an approved medical school. Psychiatric resident positions consist of nine months in psychiatry. Applicants must have successfully completed their fourth year of study in a medical school and they must have the degree of B.M. or M.D. In addition they must have completed an accredited rotating internship of at least nine months or be serving such internship at the time of making application. Persons who attain eligibility but who are still serving their internship may have their names submitted for appointment, but they cannot enter on duty until they have completed their internship. There are no age limits for this examination, and no written test will be given. Applications will be accepted until the needs of the service have been met. Application forms may be secured at first and second class post offices, from the commission's regional offices, or direct from the U. S. Civil Service Commission, Washington 25, D. C. Appointments to federal positions are made in accordance with War Manpower Commission policies and employment stabilization programs.

Sept. 23, 1944.

Patulin for the Common Cold

In November 1943 a report was published on a clinical trial of patulin, a metabolic product of the mold *Penicillium patulum*, claiming that it had given significant results in the treatment of the common cold. The results in 95 cases were considered encouraging when compared with 85 controls. The discovery of an effective treatment for the common cold being thought desirable, the Medical Research Council decided to investigate. Definition of the common cold offered considerable difficulties. There is no reason to believe that the condition is always or even usually due to the same agent. A second difficulty is that the duration of colds is variable. Third, the objective signs are too variable to serve as criteria for the presence and progress of colds. To meet the first difficulty large numbers of patients at widely separated places were used. To meet the second difficulty alternate cases were given a spurious treatment and served as controls. Therapeutic trials were carried out in eleven factories with a total population of 90,000, and in three units of the post office with a population of 15,000. The test solution was instilled into the nostrils. In all, 668 patients were treated with patulin and 680 with a control solution. No evidence was found that patulin is effective in the treatment of the common cold.

The Casualties and Damage of the Second Battle of London

London has withstood two severe bombings from the air which were entirely indiscriminate. The first and more severe was in 1940 and was made by bombing planes. The second began on June 15 of the present year and was made with flying bombs. The first ten weeks were the period of greatest intensity. The number of persons evacuated from London amounted to 818,000. At the end of June 81,000 were sheltering in the stations of the underground tube railway, but this was an improvement compared to 123,000 in September 1940. In public shelters of all kinds there were 462,000, compared to 470,000 in November 1940. The intensity of the attack at the end of June was shown by the fact that nearly half of the 400,000 houses damaged in the first two weeks had not received even a "field dressing." Early in July London began to get into its stride, and the evacuation machinery was running smoothly. Apart from those who went at their own expense there went out under government plans no fewer than 818,000 persons: 228,000 mothers and expectant mothers, 537,000 children and 53,000 old, invalid and blind. One hundred London hospitals were damaged. The growing loss of beds and the possibility of an increasing attack led to evacuation of over 14,000 patients to hospitals all over Britain. The number of flying bomb casualties admitted to London hospitals was 14,558. The work in the hospitals from the start was magnificent. The ambulance service carried 27,000 casualties, and the first aid posts with their mobile units attended to 40,000 minor cases. The special ambulance service for transferring patients from damaged hospitals to others and for the reception of overseas casualties carried 52,000 patients in the first ten weeks.

Each flying bomb destroyed or damaged an average of four hundred houses during the ten weeks. Some 51,000 people were rehoused in requisitioned houses and 57,000 were billeted. A labor force of 75,000 was engaged in repairs of houses and other buildings. Everything possible was done to see that as many homes as possible were created in the coming months. At the present time there are nearly 900,000 houses in London in need of repair from bomb damage.

National Scheme for the Diagnosis of Pulmonary Tuberculosis by Mass Radiography

The Medical Research Council's Committee on Tuberculosis in Wartime recommended that mass radiography should be under the general direction of the Ministry of Health and should not be lightly undertaken. A high standard of quality was necessary for correct interpretation, which required great radiologic skill. The Mass Radiography Subcommittee of the Minister of Health's Standing Advisory Committee on Tuberculosis laid down that, when mass miniature radiography is undertaken on a large scale, trustworthy and comparable results can be secured only from the use of carefully designed standard apparatus. The government therefore ensured that the standard apparatus which is arranged to be manufactured and supplied to selected local authorities should be of the highest quality and able to meet much greater stresses than ordinary x-ray machines.

As employers may be considering arrangements for the mass radiography of their employees, the Ministry of Health has issued a warning and pointed out that there are difficulties and dangers which may not be obvious. The primary purpose of mass radiography is not diagnosis in the ordinary sense. The object is to discover in a group of ostensibly healthy persons those who have signs indicating the possibility of incipient disease, which should be further investigated by more intensive methods. Persons who do not have ground to suspect that they are in any risk of illness must be ready to be examined. Anything that would weaken public confidence in mass radiography would therefore impair its usefulness. So also would anything that would lead the public to expect too much from this new method.

It is important to realize that mass radiography has not made the diagnosis of pulmonary tuberculosis easier; on the contrary, it brings to light many symptomless minimal cases. Recovery occurs spontaneously in numbers of these without treatment, and the prognosis in any case can be assessed only by the most careful clinical investigation and periodic supervision. As the diagnosis of tuberculosis may involve change or loss of work and may prejudice life insurance, it should be made only by experts with all the diagnostic procedures at their disposal. Provision for this is made in the national scheme operated by the health authorities. Another point is that the government's mass radiography scheme includes arrangements for collecting far more information on the incidence of tuberculosis than has ever been available before, which will be of great value in the campaign against tuberculosis. This can be assured only by a uniform scheme and a standardized system of records.

Marriages

HARRY BELLACH, Brooklyn, to Dr. ELIZABETH CORNFELD of New Haven, Conn., in Brooklyn, September 10.

WILLIAM ANDREW DALE, Columbia, S. C., to Miss Corinne Craig Howell of Nashville, Tenn., September 11.

GEORGE SHERMAN RIPLEY JR., Mount Vernon, N. Y., to Miss Phyllis E. Walch of Torrington, Conn., June 28.

WILLIAM LYMAN HUFFMAN, Cleveland, to Miss Jane Elizabeth Molin of Lakewood, Ohio, in September.

ROBERT JAMES BARNETT, Greenwood, Miss., to Miss Martha Ann Robinson in New Orleans, August 26.

WILLIAM C. CLYNE to Miss Kathryn Fitzgerald, both of New York, in Katonah, N. Y., September 11.

RAYMOND F. GRENFELL, Pittsburgh, to Miss Maude Byrnes Chisholm of Columbia, S. C., August 19.

ALVIN J. BEECHER to Miss Violet Aurelia Dionca, both of Detroit, August 12.

M. BAXTER ASNIS, New York, to Miss Elfreda M. LEONARD of Boston in May.

Deaths

Lieuten Moss Rogers • Senior Surgeon, U. S. Public Health Service, Fort Worth, Texas; University of Texas School of Medicine, Galveston, 1916; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; served as vice president of the Kentucky Psychiatric Association; entered the U. S. Public Health Service Reserve as an assistant surgeon in October 1921 and became a member of the regular corps April 5, 1922, serving at the Quarantine Station, New Orleans; accepted a commission as a first lieutenant in the U. S. Army in 1917 and served in that capacity at Kelly Field, San Antonio, Texas; went overseas in July 1918 and became battalion medical officer of a front line unit; from 1922 to the time of his death he served as public health officer in New Orleans, Washington, D. C., New Mexico, Colorado, Missouri, New York, Texas and at the American Consulate, Cobh, Irish Free State; had been associated with Dr. Joseph Goldberger in the isolation of the pellagra preventive vitamin and the determination of the pellagra preventive values of various foods; from 1936 to 1940 had been medical officer in charge of field studies in mental hygiene at Lexington, Ky.; in 1940 detailed to Springfield, Mo., Medical Center for Federal Prisoners; transferred to the Federal Reformatory at Chillicothe, Ohio, in 1941 and at about the same time was promoted to senior surgeon; remained at the institution in Chillicothe until his most recent transfer, July 1, 1944, to the U. S. Public Health Service Hospital in Fort Worth, where he died September 7, aged 53, of coronary thrombosis.

John Sinclair Dye • Waterbury, Conn.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; Columbia University College of Physicians and Surgeons, New York, 1915; fellow of the American College of Surgeons; past president of the New Haven County Medical Association and the Waterbury Medical Association; first lieutenant, Tennessee National Guard, Company B, Detached Cavalry, from 1901 to 1908; entered the medical corps of the U. S. Army during World War I as a captain and advanced to the rank of colonel after two years; after the war worked for a time in the Surgeon General's Office, standardizing the surgical services of army base hospitals in this country; later served as chief of the division of surgery in the Surgeon General's Office; colonel, medical reserve corps, not on active duty; at one time member of the board of health in Chattanooga, Tenn., where he was chief of staff of the Erlanger Hospital from 1908 to 1914; chief surgeon at the Chase Brass and Copper Company; on the staffs of St. Mary's Hospital and the Waterbury Hospital, where he died August 9, aged 67, of coronary occlusion with pulmonary embolism and infarction.

Walter Hughson • Chestnut Hill, Pa.; Johns Hopkins University School of Medicine, Baltimore, 1918; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otolological Society, American Otolological Society, Inc., and the American Association of Anatomists; formerly assistant and instructor in anatomy, associate in applied anatomy and surgery, associate professor of surgery and associate surgeon, associate in clinical surgery, associate in research otology and associate professor of otology at the Johns Hopkins University School of Medicine, Baltimore; served as assistant visiting surgeon to the Johns Hopkins Hospital, Baltimore; instructor in otolaryngology at the University of Pennsylvania School of Medicine and associate in otology at the University of Pennsylvania Graduate School of Medicine, Philadelphia; consultant to the Bureau of Child Hygiene, U. S. Public Health Service; since 1935 director of the otologic research laboratory at the Abington Memorial Hospital, Abington, where he died September 13, aged 53, of pneumococcal meningitis.

Robert Bennett Bean, Charlottesville, Va.; Johns Hopkins University School of Medicine, Baltimore, 1904; retired in 1942 as professor of anatomy at the University of Virginia Department of Medicine, where he had been since 1916; assistant in anatomy at his alma mater, 1904-1905; instructor of anatomy at the University of Michigan, Ann Arbor, from 1905 to 1907; formerly director of the anatomic laboratory and associate professor of anatomy at the Philippine Medical School, Manila; at one time associate professor of anatomy and professor of Gross anatomy at the Tulane University School of Medicine, New Orleans; served as president of the New Orleans Academy of Sciences; fellow of the American

Association for the Advancement of Science; member of the American Association of Anatomists and the American Anthropological Association; corresponding member of the Societa Romana Antropologia; author of "Racial Anatomy of the Philippine Islanders," 1910, "Races of Man," 1932, and "Peopling of Virginia"; died in Staunton August 27, aged 70, of cerebral arteriosclerosis and cerebral hemorrhage.

John Borneman Ludy • Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1906; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; demonstrator of dermatology at the Jefferson Medical College; served during World War I; colonel, medical reserve corps, U. S. Army, not on active duty; author of "Atlas of Skin Disease"; received an honorary degree of doctor of science from the Franklin and Marshall College, Lancaster, Pa.; consulting dermatologist to the Delaware County Hospital, Drexel Hill, and Norristown State Hospital, Norristown; dermatologist, American Oncologic Hospital, Hospital of the Protestant Episcopal Church, Lankenau Hospital, Methodist Hospital, Philadelphia General Hospital, Pennsylvania Hospital and the Abington Memorial Hospital, Abington, Pa., where he died September 11, aged 64, of cardiovascular disease.

Hermann Bertram Gessner • New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1895; since 1936 professor of clinical surgery, emeritus, at his alma mater, where he had been lecturer and demonstrator of operative surgery, professor of operative surgery and clinical surgery and professor of clinical surgery; president of the Louisiana State Medical Society, 1930-1931, and the Orleans Medical Society in 1902; member of the Southern Medical Association and the Southern Surgical Association; fellow of the American College of Surgeons; acting assistant surgeon in the U. S. Public Health Service in 1897 and 1905; veteran of the Spanish-American War; first lieutenant in the medical reserve corps of the U. S. Army from 1909 to 1917; served on the Mexican Border in 1916; for many years on the staffs of the Charity Hospital and the Touro Infirmary; author of "Laboratory Exercises in Operative Surgery"; died August 31, aged 72, of coronary thrombosis.

Ned Rudolph Smith • Tulsa, Okla.; University of Michigan Medical School, Ann Arbor, 1921; member of the American Psychiatric Association and the Southern Medical Association; past president and trustee of the Tulsa County Medical Society; president of the city board of health; in 1926 joined the staff of the Hertzler Hospital and Clinic in Halstead, Kan., where he had been in charge of the neurology and psychiatry work; medical director of the Oakwood Sanitarium; served as psychiatrist at the Tulsa Induction Center for one year; member of the chamber of commerce and the Kiwanis Club; on the editorial board of the *Journal of the Oklahoma State Medical Association*; on the staffs of the Hillcrest Memorial Hospital and St. John's Hospital, where he died August 18, aged 60, of coronary thrombosis.

Max Harold Hoffman • St. Paul; University of Minnesota Medical School, Minneapolis, 1921; since 1937 clinical assistant professor of medicine at his alma mater, where he had been assistant in medicine from 1922 to 1924 and instructor from 1925 to 1936; specialist certified by the American Board of Internal Medicine; member of the Central Society for Clinical Research, Minnesota Academy of Medicine and the Minnesota Pathological Society; in 1941 president and formerly vice president and secretary-treasurer of the Minnesota Society of Internal Medicine; visiting physician to the Ancker Hospital, Charles T. Miller Hospital and St. Joseph's Hospital; died August 22, aged 48, of coronary heart disease.

John Janney Lloyd • Rochester, N. Y.; University of Virginia Department of Medicine, Charlottesville, 1903; specialist certified by the American Board of Internal Medicine; member of the American College of Chest Physicians, National Tuberculosis Association and the American Clinical and Climatological Association; for many years medical director of the Monroe County Tuberculosis Sanatorium; at one time resident physician of Catawba Sanatorium, Catawba Sanatorium, Va.; consultant in tuberculosis to the Strong Memorial Hospital and consulting physician to the Rochester General Hospital; consultant, silicosis board, state department of labor; died September 22, aged 65, of cerebral thrombosis.

Edwin Dial Watkins, Memphis, Tenn.; Columbia University College of Physicians and Surgeons, New York, 1906; served an internship at the Presbyterian Hospital, New York; specialist certified by the American Board of Ophthalmology;

fellow of the American College of Surgeons; formerly associate professor of gynecology and clinical assistant and assistant in ophthalmology at the University of Tennessee College of Medicine; served during World War I; formerly on the staffs of the Baptist Memorial Hospital and Memphis Eye, Ear, Nose and Throat Hospital; died in the Veterans Administration Facility July 31, aged 62, of cirrhosis of the liver.

Benjamin Everett Reeves, West Jefferson, N. C.; College of Physicians and Surgeons, Baltimore, 1891; coroner of Ashe County; Ashe County physician for prison, poorhouse and state prison camp; member of the board of trustees for the North Carolina schools for the deaf and blind; medical examiner for the draft board of the county during World War I and II; assistant surgeon for the Norfolk and Western Railway; president of the First National Bank; served on the county road commission, town council and school committee and in the state legislature; died August 30, aged 77, of heart disease.

Claude Vernet Davis • Pennsville, Ohio; Ohio State University College of Medicine, Columbus, 1917; served an internship at the St. Luke's Hospital, Cleveland; president of the Ohio State Medical Board, serving at one time as vice president and member of the board; president of the Morgan County Medical Society; member of the Morgan County Draft Board; served at Base Hospital number 123 near Mars, France, during World War I; on the staff of the Memorial Hospital, Marietta, where he died August 16, aged 57, of cerebral hemorrhage.

Moody Warren Arnold • New York; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; medical superintendent of the Home for Incurables; died in the New York Post-Graduate Medical School and Hospital August 21, aged 56, following an operation for carcinoma of the duodenum and pancreas.

Jacob Axelrad, New York; Columbia University College of Physicians and Surgeons, New York, 1908; died August 10, aged 63, of coronary thrombosis.

Webster A. Becher, North Industry, Ohio; University of Wooster Medical Department, Cleveland, 1902; member of the Ohio State Medical Association; served on the staff of the Mercy Hospital in Canton; died August 1, aged 76, of coronary infarction.

William Wheeler Bolster • Lewiston, Maine; Medical School of Maine, Portland, 1908; formerly assistant professor of physiology at his alma mater; at one time a member of the school board in Auburn; for many years on the staff of the Central Maine General Hospital, where he died August 11, aged 70, of cerebral hemorrhage.

Albert James Bower • Greenville, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; fellow of the American College of Surgeons; served during World War I; on the staff of the United Memorial Hospital; died August 15, aged 63, of coronary heart disease.

Robert Boyd, Brooklyn; College of Physicians and Surgeons, New York, 1891; veteran of the Spanish-American War; died in the Cumberland Hospital August 1, aged 74, of coronary thrombosis.

Glenn Zimmerman Brant • Berlin, Pa.; Temple University School of Medicine, Philadelphia, 1936; served an internship at the Harrisburg Polyclinic Hospital, Harrisburg; on the staff of the Somerset Community Hospital, Somerset; first lieutenant in the medical reserve corps of the U. S. Army from March 1, 1941 to Jan. 5, 1943; died in Bristol Bay, Alaska, May 19, aged 34, of suffocation by smoke.

James Frank Brooke • Colonel, U. S. Army, retired, Greenville, N. C.; Kansas City Hahnemann Medical College, Kansas City, Mo., 1903; U. S. Army Medical School, 1921; commissioned a first lieutenant in the medical corps of the U. S. Army on Nov. 22, 1918; later promoted to captain, major, lieutenant colonel and colonel; retired Feb. 29, 1944; formerly post surgeon at Bolling Field, Anacostia, D. C.; died August 9, aged 64, of coronary occlusion.

John Bernard Brown, Paxton, Ill.; Illinois Medical College, Chicago, 1902; died September 12, aged 68, of coronary occlusion.

Charles O. Burgess, Monmouth, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the Illinois State Medical Society; formerly deputy coroner for Warren County; served as a member of the pension examining board for veterans; on the staff of the Monmouth Hospital; died August 24, aged 68, of carcinoma.

Aaron Fenton Burson, Oakwood, Ohio; Eclectic Medical College, Cincinnati, 1910; member of the Ohio State Medical Association; served during World War I; was killed August 8, aged 59, in an automobile accident.

George Barnes Case, Syracuse, N. Y.; Syracuse University College of Medicine, 1909; member of the Medical Society of the State of New York; died August 11, aged 60, of probable coronary thrombosis.

Ferdinand Chenik • Detroit; Detroit College of Medicine and Surgery, 1924; fellow of the American College of Chest Physicians; a founder and formerly medical superintendent of the Chenik Hospital; author of "White Plague"; died near Westlaco, Texas, August 15, aged 51.

Hiram Edward Cleveland • Burlington, Wash.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; member of the North Pacific Surgical Association; fellow of the American College of Surgeons; past president of the Washington State Medical Association; served as chief of staff, Burlington General Hospital; local surgeon for the Great Northern Railway; member of the chamber of commerce; died August 21, aged 69, of arteriosclerotic heart disease.

James William Craddock • Louisville, Ky.; Kentucky School of Medicine, Louisville, 1904; died in the Kentucky Baptist Hospital August 1, aged 65, of bronchopneumonia.

William David Culin, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1894; associate professor emeritus of gynecology at his alma mater; fellow of the American College of Surgeons; consulting gynecologist at the Women's Homeopathic Hospital; died August 24, aged 80, of coronary thrombosis.

Oscar H. Damron • Silex, Mo.; Keokuk (Iowa) Medical College, 1896; died August 30, aged 74, of angina pectoris.

Edward Davenport, Hopkinsville, Ky.; University of Louisville Medical Department, 1901; member of the Kentucky State Medical Association; clinical director of the Western State Hospital; formerly superintendent of the Eastern State Hospital, Lexington; died August 22, aged 60, of coronary occlusion.

Harry Edward W. Fenton, Ancon, C. Z.; University of Louisville (Ky.) School of Medicine, 1929; served an internship at the Gorgas Hospital; diplomate of the National Board of Medical Examiners; member of the Medical Association of the Isthmian Canal Zone; first lieutenant in the medical reserve corps of the U. S. Army, not on active duty; since 1930 employed as physician by the health department of the Panama Canal Zone; died August 17, aged 37, of adrenal hemorrhage.

Howard Sinnickson Forman, Lee, Mass.; Columbia University College of Physicians and Surgeons, New York, 1896; served during World War I; formerly on the staff of the Christ Hospital, Jersey City, N. J.; member of the Rotary clubs of Lee and Jersey City; died in the House of Mercy Hospital, Pittsfield, September 19, aged 73, of cerebral hemorrhage following an operation.

Clare Edwin Fraunfelter • Canton, Ohio; Rush Medical College, Chicago, 1904; past president of the Stark County Medical Society; for many years a member of the staff of the Aultman Hospital, serving as president for several terms; died September 5, aged 67, of cerebral thrombosis.

Abbott James Fuller • Pemaquid, Maine; University of Vermont College of Medicine, Burlington, 1907; secretary of the Knox County Medical Society; served as an officer in the U. S. Army during World War I; member of the staffs of the Knox County General Hospital in Rockland and the Miles Memorial Hospital in Damariscotta; died August 18, aged 59, of cerebral hemorrhage.

Byron Edgar Giannini, Shepherdsville, Ky.; University of Tennessee Medical Department, Nashville, 1905; member of the Kentucky State Medical Association; died August 4, aged 62, of heart disease.

Orla Hilliard Gillett • Grand Rapids, Mich.; University of Michigan Medical School, Ann Arbor, 1923; fellow of the American College of Surgeons; on the staffs of the Butterworth and Blodgett Memorial hospitals; served an internship, a residency and as chief of surgery at St. Mary's Hospital, where he died August 2, aged 51, of cerebral hemorrhage.

Gordon Parker Goodfellow • East Orange, N. J.; Detroit College of Medicine and Surgery, 1929; captain, medical corps, Army of the United States, from Aug. 8, 1942 to Dec. 1, 1943; on the staff of the East Orange General Hospital,

where he died July 25, aged 40, of coronary thrombosis and vascular disease

Mark Gordon, Brooklyn, Baltimore Medical College, 1900; for many years attending physician and chief of clinic at the Beth-El Hospital, died August 17, aged 70, of coronary thrombosis

Theodosia S. Fowler Johansen, Morristown, N. J.; Eclectic Medical College of the City of New York, 1901, died in the Muhlenberg Hospital, Plainfield, July 27, aged 73, of cerebral embolism and carcinoma of the uterus

John Allen Johnston @ Fort Lauderdale, Fla., University of Georgia Medical Department, Augusta, 1908, president of the Broward County Medical Society, formerly assistant professor of anatomy at his alma mater, at one time health officer of Bainbridge and Lafayette, Ga., chief of obstetric staff, Broward General Hospital, where he died August 21, aged 60, of cardiac asthma and pneumonia

Wilbur Merriam Judd @ Greystone Park, N. J., University of Vermont College of Medicine, Burlington, 1927, resident physician at the New Jersey State Hospital, died September 1, aged 42, of cerebral hemorrhage

William George Martin @ Columbus, Ohio, University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1911, for many years medical examiner for the Norfolk and Western Railroad Company, died in the White Cross Hospital August 30, aged 56, of cerebral hemorrhage

Benjamin F. Matheny @ Parsons, W. Va., Baltimore University School of Medicine, 1906, served as coroner of Harrison County, on the staff of the Tucker County Hospital, died September 8, aged 65, of coronary occlusion

Aloysius Alphonsus Mulligan, Harrison, N. J., Baltimore Medical College, 1905, died July 9, aged 63, of cardiovascular renal disease.

Henry Alphonse Paradis @ Sparks, Nev., Baltimore University School of Medicine, 1901; past president of the Nevada State Medical Association; member of the Pacific Association of Railway Surgeons, for many years division surgeon, Southern Pacific Company; served during World War I, at one time health officer of Sparks, member of the staffs of the St. Mary's and Washoe County General hospitals in Reno, died August 10, aged 66, of bronchogenic carcinoma

Harlow Orville Shockley, Darlington, Wis., Rush Medical College, Chicago, 1899, served an internship at the Presbyterian Hospital, Chicago, past president and secretary of the Lafayette County Medical Society; mayor of Darlington for seven years, president of the First National Bank of Darlington, died August 16, aged 71, of coronary thrombosis and chronic nephritis

Daniel Dewitt Van Voorhis, Beecher, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1893; for many years surgeon for the Chicago and Eastern Illinois Railroad, killed September 12, aged 70, when the automobile in which he was driving was struck by a truck

John T. Warford @ Lansing, Mich., Medical Department of Tulane University, New Orleans, 1891, member of the staff of the Edward W. Sparrow Hospital, died in Philadelphia July 30, aged 75, of acute cardiac failure

Herbert Tiffany Weston, West Hartford, Conn., Baltimore Medical College, 1890, for many years connected with the professional liability division of the Aetna Life Insurance Company, died in Hartford July 28, aged 75, of heart disease

Clarence Leon Wilson, Chicago, University of Illinois College of Medicine, Chicago, 1920, member of the Illinois State Medical Society, specialist certified by the American Board of Obstetrics and Gynecology; field consultant, division of maternal and child hygiene, State of Illinois Department of Public Health, senior associate attending obstetrician to the Provident Hospital, died August 28, aged 49, of carcinoma

John Russell Woods, Columbus, Ohio, Ohio Medical University, Columbus, 1904, died July 10, aged 63, of cerebral hemorrhage

Robert Elmore Wright @ Dallas, Texas, Atlanta College of Physicians and Surgeons, 1913; specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology, Texas Ophthalmological and Otolaryngological Society, Dallas Academy of Ophthalmology and Otolaryngology, Southern Clinical Society and the Southern Medical Association, served as president of the general staff of the Medical Arts Hospital, died July 11, aged 57, of cardiorenal disease

DIED IN MILITARY SERVICE

Elmer Barney M. Casey @ St. Louis; National University of Arts and Sciences Medical Department, St. Louis, 1917, served during World War I, commissioned a captain in the medical reserve corps of the U. S. Army on Nov. 28, 1924, later promoted to major and lieutenant colonel; began active duty on July 15, 1941; died in the Walter Reed General Hospital, Washington, D. C., July 25, aged 51, of carcinoma of the intestine

James Halbert Gambrell, El Paso, Texas, Baylor University College of Medicine, Dallas, 1910, served an internship at St. Paul's and Baylor hospitals in Dallas, formerly instructor of surgery at his alma mater, served as chief of staff of the Masonic and El Paso County hospitals, formerly member of the city school board, in 1916 accepted a commission as lieutenant in the medical corps of the Texas National Guard and served on the Texas-Mexican border during the punitive campaign against Pancho Villa, served with the 36th division in France during World War I, commissioned a major in the medical reserve corps of the U. S. Army on Oct. 7, 1919, later promoted to lieutenant colonel and colonel, began active duty as a colonel on Jan. 21, 1942, served as commanding officer of the 51st, 67th and 96th General hospitals when these units, each in turn, were activated and trained for overseas duty, medical training officer of the military training division of the Eighth Service Command in Dallas, where he died April 23, aged 59, of coronary arteriosclerosis and coronary thrombosis

William Arthur Johnson @ Uniontown, Pa.; University of Pittsburgh School of Medicine, 1935, served an internship at the Pittsburgh Medical Center; interned and served as assistant resident in obstetrics and gynecology at the New York Hospital, served a residency in obstetrics at the New York Polyclinic Medical School and Hospital in New York; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on June 5, 1935, began active duty on Dec. 5, 1940, promoted to captain in November 1941 and major in November 1942, went overseas in December 1943, killed while on duty as a flight surgeon in Gunnislake, England June 11, aged 32, in an aircraft accident

James Patrick Jordan, North Tonawanda, N. Y., St. Louis University School of Medicine, 1932, member of the Medical Society of the State of New York, diplomate of the National Board of Medical Examiners, member of the National Gastroenterological Association, specialist certified by the American Board of Internal Medicine, served an internship at the Buffalo Hospital of the Sisters of Charity and a residency in medicine at the Millard Fillmore Hospital, Buffalo, commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve on Sept. 5, 1942 and began active duty on Oct. 26, 1942, had been assigned to the Office of Naval Officer Procurement in Rochester, N. Y., died in the South Atlantic area off the coast of South America July 23, aged 44, of bronchopneumonia

Joshua Levitsky @ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1936; served an internship at the Mount Sinai Hospital, commissioned a first lieutenant in the medical corps, Army of the United States on Oct. 21, 1942, later promoted to captain, began active duty on Dec. 10, 1942, died in England, April 25, aged 31, as the result of injuries received in an airplane crash

Harry Meyer @ New York, University and Bellevue Hospital Medical College, New York, 1922, served an internship at St. Mark's Hospital, commissioned a major in the medical corps, Army of the United States, on Sept. 11, 1942, died in the Lawson General Hospital, Atlanta, Ga., August 4, aged 47, of malignant hypertension

Allen Sydney Morris, Buffalo, University of Buffalo School of Medicine, 1926, member of the Medical Society of the State of New York, interned at the Buffalo City Hospital; served on the staff of the Millard Fillmore Hospital, formerly connected with the city health department, commissioned a captain in the medical corps of the Army of the United States on July 27, 1942, later promoted to major, died at Camp Rucker, Ala., August 31, aged 43, of myocardial failure

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the
Food and Drug Administration of the
Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment]

Armi Mineral Water.—Ralph R. Markwood, trading as Armi Mineral Water Company, Toledo, Ohio. Shipped July 2 and August 15, 1940. Substantial amounts of sodium sulfate and lime, not more than 0.15 grain of silicon dioxide per quart (declared an insignificant quantity present in many city water supplies) and only traces of, if any, potassium diplophosphate, manganese and potassium chlorides, magnesium, calcium, sodium and ferric phosphates, potassium iodide or lithium bromide. Misbranded because label falsely represented product to contain important and substantial amounts of the substances in the last named group. Also misbranded because label did not give the common or usual name of each active ingredient, since one of them was slaked lime, which label listed as calcium hydroxide. Further misbranded because label did not so list ingredients as to make them understood by the ordinary individual, with the exception of lime and sodium sulfate, which were present, if at all, in unimportant and inconsequential proportions. Misbranded again because of misleading zigzag design on label depicting lightning, and because the statement "Treated By Electrolysis" failed to reveal that any treatment by electrolysis to which the article may have been subjected had not affected its properties. Misbranded, finally, because label claim, "Scientifically Balanced," was false and misleading when applied to water to which had been added small amounts of lime and sodium sulfate and inconsequential amounts of other substances—[D.D.N.J., F.D.C. 777; September 1943.]

Floramucin.—Lawrence M. Williams, trading as Lawrence Laboratories, Chicago. Shipped Jan. 27 and March 7, 1941. Composition essentially the mucilaginous portion of psyllium seed, with karaya gum, sugar and dextrin. Misbranded because of misrepresentation that it would detoxify and be efficacious in treating biliousness, sore stomach, indigestion, intestinal stasis, excess gas, colitis, torpid liver, and stomach and bowel troubles; that it would combat constipation and colitis without laxatives, thus implying that it was not a laxative, that it would keep the digestive tract vigorous and healthy, insure quick and effective relief from faulty elimination, and do some other things, that it was not a drug or laxative, did not contain a gum, and was more than a bulk producing laxative—[D.D.N.J., F.D.C. 766, September 1943.]

Howell's Cocoa & Quinine Syrup.—Howell Company, Inc., New Orleans. Shipped between Feb. 21, 1940, and Jan. 6, 1941. Composition labeled to contain 2 grains of quinine sulfate per teaspoonful, whereas only 1.65 grains were found by analysis. Hence misbranded—[D.D.N.J., F.D.C. 807, December 1943.]

Mentho-Thymoline.—Standard Drug Company, Inc., Spartanburg, S. C. Shipped Feb. 28 and March 13, 1941. Composition: essentially a mixture of small amounts of camphor, menthol and thymol, incorporated in a petrolatum base. Misbranded because labeling falsely represented product as a cure or treatment for inflammations, colds, croup, sore throat, burns, wounds, hemorrhoids, headache and earache, further misbranded because the name Mentho-Thymoline was misleading in suggesting that the product consisted solely of menthol and thymol, whereas it contained other active ingredients; also misbranded because label did not accurately declare the quantity of the contents—[D.D.N.J., F.D.C. 805, December 1943.]

Pitcher's Castoria.—Roma Extract Company, Inc., Boston. Shipped, Nov. 10, 1941. Composition essentially extracts of plant drugs, including senna, Rochelle salt (approximately 0.28 per cent), sodium bicarbonate (2.5 per cent), santonin (0.027 per cent) and flavoring materials, including methyl salicylate, with sugar and water. Misbranded because of false label claims: "A Reliable Remedy for . . . Diarrhea due to Constipation, Worms, and Promotes Sleep by Overcoming these Disorders," further misbranded because active ingredients were not listed on label in such terms as to make them easily understood by the ordinary individual. Also misbranded because label did not give the common or usual name of each active ingredient; misbranded, finally, because container was so made and filled as to be misleading, since carton was materially larger than necessary to hold the bottle—[D.D.N.J., F.D.C. 782, September 1943.]

Vi-Penta Drops 'Roche'.—Hoffman-La Roche, Inc., Nutley, N. J. Shipped April 22, 1941. Composition, less than the claimed 9,000 units of vitamin A per 0.6 cc. Adulterated and misbranded for this reason. Also misbranded because falsely represented as efficacious for malnutrition, infections, anemias, tuberculosis, typhoid fever, diarrhea, colitis, diabetes, catarrhal jaundice, certain skin diseases (such as eczema), prophylaxis of abnormal dentition, and periods of vomiting, such as in infancy, childhood or pregnancy—[D.D.N.J., F.D.C. 774, September 1943.]

THE RELIEF OF PAINFUL THIGH STUMP AND SCIATICA

To the Editor:—In THE JOURNAL, April 8, page 1030, in his article on "Pain After Amputation and Its Treatment," Dr. J. C. White writes "In this discussion of intractable pain which may follow amputation I should like to begin by pointing out how little is known about it, and what an opportunity is awaiting surgeons in the military forces today for gaining a better insight into its mechanism, as well as for devising effective methods of treatment." The following case seems pertinent:

An aviator aged 30 crashed five years previously, the injury requiring supracondylar amputation of the right thigh; a few weeks later the stump became painful and was injected with saline solution. Then the sciatic nerve was alcoholized and one year later 4 inches of it was removed, but without relief, and he took to narcotics. On Jan. 27, 1944 he was suddenly seized with an excruciatingly severe and almost unbearable pain in the stump and was then referred to me by Coroner T. C. Goraczewski. He came in at 10 p. m. suffering agonizing pain in the sciatic nerve with tonic contraction of the hamstrings, which aggravated the pain. Employing a technic I devised and have been successfully using in sciatica I searched for and found a wining spot of tenderness over the sacral origin of the sacrospinalis in the dorsal hollow of the sacrum and injected it with 1 cc. of 2 per cent procaine hydrochloride, with instantaneous relief of the pain and disappearance of the tonic spasm. At the time of this writing (September 18) the patient states that the relief has been maintained, including freedom from the tickling sensations in the phantom ankle and toes of the amputated limb.

I suggest the following mechanism as being operative in these cases: In response to a peripheral irritation the piriformis and obturator internus (with the gemelli), from between which the sciatic nerve emerges, become spastic and pinch the nerve. This peripheral irritant is removed by anesthetization of the posterior sacral plexus, whose fibers emerge from the upper four sacral foramina to enter the multifidus to supply it with motor fibers. Relief of the ordinary case of sciatica ensues quite regularly in seven minutes when clocked, and as the pain vanishes muscle stiffness or spasm disappears and pain present in the hip joint or knee joint is relieved. In some cases there will be a tender spot over each of the upper four sacral foramina, each requiring an injection. In this region I use a 1 inch needle (preferably a B-D Huber point, which is much less painful to introduce) attached to an ordinary hypodermic syringe (I prefer a tuberculin syringe): the needle is boldly plunged through each tender spot up to its hilt so as to reach the multifidus and therefore the fibers of the posterior sacral plexus, and from 0.5 to 1 cc. of 2 per cent procaine is deposited for each spot.

The following case of sciatica in civilian practice exemplifies the suggested etiology and treatment:

H. F., a man aged 53, an electrical engineer, referred by Dr. Harry Goldblatt of the Western Reserve University Medical School, Cleveland, walked into the office with an obviously painful limp on the left side. He stated that on July 27, 1944 after a sudden, peculiar twist when lifting a 25 pound bag a pain was suddenly felt low in the back on the left side and became excruciatingly severe. Twenty-four hours after treatment by a physical therapist on August 25 pain began in the left sciatic nerve, and the left foot began to drag. His present (September 20) complaint is of pain in the left sciatic nerve, constant, stabbing and aching, not aggravated by coughing or sneezing. There is numbness of the foot from its sole up along the outer side of the left leg to about its middle, with partial foot-drop and inability to extend the toes. Wincing tenderness

is present over the left sacroiliac joint and over the posterior sacral foramina on the same side. The joint was injected with 1 cc. of 2 per cent procaine hydrochloride, as was each sacral wincing spot. Ten minutes later the patient could weakly extend the toes and walk without a limp, and he noticed that the numbness was leaving the foot, outer side first. Examination on the succeeding three days showed continued improvement and finally complete relief from all symptoms.

This situation can definitely be explained by assuming a minor strain of the sacroiliac joint as the peripheral irritant for spasm of the piriformis and obturator internus via the sacral plexus squeezing between them the sciatic nerve and producing a full blown sciatica. Injection of the joint and wincing spots released the grip of the muscles on the nerve, with clearance of the symptoms and signs.

Of late I have been substituting this method for lumbar sympathetic plexus block in cases of vascular disturbances of the lower extremity, the results of which I shall report later. I sincerely hope that these same results will be obtained in the hands of others if so our boys with painful thigh stumps can avoid the formidable operations Dr. White (unwillingly I am sure) finds it necessary to practice, while in civil practice the at times hazardous direct blocking of the sciatic nerve itself may be avoided.

P. G. SKINNER, M.D. South Bend Ind.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals Not for Profit: State Unemployment Compensation Act Not Applicable to Charitable Hospital.—The Scripps Memorial Hospital, Inc., is a nonprofit organization organized under the laws of the state of California conducting a hospital, a metabolic clinic and a dietetic school. In accordance with the purposes for which it was founded, it treats persons regardless of race, creed or ability to pay, although it receives pay from about 75 per cent of the patients admitted, a full charge being made to patients with the ability to pay, a lesser charge being made in proportion to a patient's ability to pay and no charge being made if the patient is unable to pay. All sums received from the care of patients are used in the maintenance of the hospital and no profit from the hospital's operation has been used for any other purpose. Sometime subsequent to the adoption of the federal social security act appropriate federal officials ruled, in accordance with provisions in the law that authorize an exemption for such a corporation, that the corporation was exempt from the payment of the taxes required by title IX of that act (the title that was designed to aid the several states in the operation of systems of unemployment compensation) on the ground that the hospital corporation was exclusively organized and operated for charitable purposes and that no portion of its funds inures to the benefit of any private individual or shareholder. In 1936 the corporation was exempted also from the payment of taxes under the California unemployment compensation act by reason of section 7 (g) of that act, which exempts from the payment of taxes "a corporation, community chest, fund or foundation, organized and operated exclusively for religious, charitable, scientific, literary or educational purposes or for the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private shareholder or individual."

In 1941 the California employment commission revoked this exemption but granted an exemption under a section added in 1939 to the California unemployment compensation act namely section 7 (k), which grants an exemption to a nonprofit organization, nonprofit safety organization, chamber of commerce service club or fraternal organization not subject to a tax under title IX of the social security act. In March 1942 the commission revoked that exemption and the hospital corporation paid unemployment compensation taxes under protest. Subsequently it instituted three suits to recover the taxes so paid all of which actions were consolidated for trial. The trial court held that the hospital was exempt from paying taxes under both sections 7 (g) and 7 (k) of the unemployment compensation act and entered a judgment for the corporation. The commission then appealed to the district court of appeals fourth appellate district which affirmed the judgment in favor of the

hospital (*Scrapps Memorial Hospital, Inc. v California Employment Commission* 143 P (2d) 364). On further appeal the Supreme Court of California affirmed the judgment of the district court of appeal and adopted, in toto, as its decision the opinion rendered in the intermediate court.

The employment commission contended that the hospital corporation was not entitled to exemption as an organization exclusively organized and operated for charitable purposes because only a small part of its operations were purely charitable in the sense that they are services rendered gratuitously to persons that are unable to pay therefor. But, answered the court, it has generally been held that the fact that fees are charged by an institution such as the hospital here involved is not controlling if those fees go to pay the expenses of operation and not to the profit of the founders or shareholders. It is also usually held that it is immaterial that such an institution is supported in part by full pay or part pay patients and that it is the use to which any profit or income is devoted which is controlling. The court thought it clear that the hospital was intended to be included in the exemption provided in the unemployment compensation act.

In defining the phrase, continued the court, "operated exclusively for . . . charitable . . . purposes" as used in the act, in conformity with the purpose of the law makers, the context and surrounding provisions of that section should not be overlooked. Among the organizations which are to be exempted are community chests and funds or foundations which ordinarily include in their scope and operations many things aside from the relief of the poor and needy, in the strictest sense of the word charity. Again, the organizations to be exempted include also those organized and operated for religious, scientific, literary or educational purposes, and even those for the prevention of cruelty to children or animals. The wide and varied nature of the exemptions thus provided rather clearly indicates a purpose and intention to give the words here in question a broad rather than a strict meaning, and that it was intended, for exemption purposes, to apply the sort of standards to charitable institutions that are applied to the others named. In the broader meaning of charitable purposes the general principle usually applied in cases in this and other states is that such an institution as a hospital, in order to come within the meaning, must be one that is open to all persons irrespective of race, color, creed or ability to pay and must be one from which no individual or entity may benefit or profit from its operations or assets on dissolution. That the legislative purpose and intention in adopting the language used in the section under discussion were as we have suggested is also indicated by the fact that, although the employment commission had for some years thus interpreted this section, as shown by its exemption of the hospital through all those years, the legislature in extensively revising the unemployment compensation act in 1939 made no change in that regard but instead enlarged the scope of such exemptions by adding a new subsection 7 (k). That new section provided for an additional exemption with respect to nonprofit organizations, nonprofit safety organizations, chambers of commerce, service clubs and fraternal organizations which are not subject to tax under title IX of the social security act.

That this was the intention of the legislature, continued the court, is further indicated by the fact that this act was adopted as a part of a plan for a uniform system of unemployment compensation then proposed and later adopted by the federal government in practically all of the American states. The language used in section 7 (g) of the section providing exemption for charitable organizations, is practically identical with that used in similar sections of the federal legislation and that of many states and is precisely similar to the language used in other federal statutes that have been in effect for many years. For that reason the interpretation placed on the language by the federal and other courts is unusually persuasive here. In passing on practically the same language in a case involving quite similar facts the Supreme Court of the United States in *Irinidad v Sagrada de* 263 U S 578 44 S Ct 204 said

The exceptions covered, among others any corporation "organized and operated exclusively for religious, charitable, scientific or educational purposes no part of the net income of which inures to the benefit of any private stockholder or individual . . ."

Two matters apparent on the face of the clause go far toward settling its meaning. First, it recognizes that a corporation may be organized and operated exclusively for religious, charitable, scientific or educational purposes and yet have a net income. Next, it says nothing about the source of the income but makes the destination the ultimate test of exemption.

That the transactions yield some profit is in the circumstances a negligible factor. Financial gain is not the end to which they are directed.

Our conclusion is that the plaintiff is organized and operated exclusively for religious, charitable and educational purposes within the meaning of the excepting clause.

In passing on a similar question involving the same language as used in the New York unemployment compensation act the court said in *re Mendelsohn*, 262 App Div 605, 31 N Y S (2d) 435.

The record shows that the hospital was organized exclusively for hospital purposes and is engaged exclusively in operating a hospital of a nonprofit character.

That fees are charged by a university or hospital is not controlling as to its being a charity, for only when such income is devoted to the profit of the founders and not used to carry on the work by adding to the endowment, etc., does it show the institution is a business and not a charity.

"A hospital association not conducted for profit which devotes all of its funds including those received from patients, exclusively to the maintenance and improvement of the institution is, therefore a charity in every sense of the word."

Charitable purposes include nonprofit hospital corporations, organized and operated exclusively for hospital purposes irrespective of whether they charge their benefactors for their services and facilities.

The same interpretation has been given this or similar language in *Virginia Mason Hospital Ass'n v Larson*, 114 P (2d) 976, and *Commissioner of Internal Revenue v Battle Creek*, 126 F (2d) 405.

For the reasons stated the finding of the trial court that the hospital corporation was entitled to exemption from the payment of taxes under the unemployment compensation act was affirmed.—*Scrapps Memorial Hospital, Inc. v California Employment Commission*, 151 P (2d), 109 (Calif, 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Relationship of Tonsils and Adenoids to Poliomyelitis.

—Lucchesi and LaBocchetta investigated the question of whether the presence or absence of tonsils has any relationship to the type or mortality of poliomyelitis. The material for the study included 432 patients admitted to the Philadelphia Hospital for Contagious Diseases with diagnosis of acute anterior poliomyelitis from 1937 to 1942 inclusive. The authors apply the term "spinal poliomyelitis" to designate the condition in which only the spinal cord is involved. The term "bulbar poliomyelitis" is used when cranial nerves alone are involved. The condition in which both the cranial nerves and the spinal cord are involved is classified as "bulbospinal poliomyelitis." There were 19 patients under 6 years of age who had had their tonsils and adenoids removed and 8 of these children had bulbar involvement. Of 161 patients in the nonadenoidotomized group under 6 years of age only 13 had bulbar involvement. Eighteen of 432 patients died. Of these 3 had bulbar, 5 had spinal and 10 had bulbospinal poliomyelitis. Fourteen of the patients who died had had tonsillectomy and adenoidectomy. The authors analyze the types of poliomyelitis occurring in 164 adenoidotomized patients and in 263 patients with intact tonsils and adenoids. Over 70 per cent of the patients with bulbar poliomyelitis and 61 per cent of those with bulbospinal poliomyelitis had had an adenoidotomectomy, while only 30.9 per cent of the patients with only spinal involvement had had their tonsils and adenoids removed. Nonparalytic poliomyelitis occurred in about equal proportions in the two groups. The consistency of the data adds weight to the belief that a positive correlation exists between absence of pharyngeal lymphoid tissue and involvement of the higher centers in poliomyelitis. Some believe that an adenoidotomectomy must occur within the incubation period of the disease in order to have any effect on the course of the illness. The evidence presented here

suggests that the absence of tonsils and adenoids increases the risk of bulbar and bulbospinal involvement in persons with poliomyelitis. Consequently the indiscriminate removal of tonsils and adenoids should not be condoned.

Sulfadiazine in Diarrhea in Children.—Menclaca employed sulfadiazine in infantile diarrhea. Most of his patients had severe or moderate diarrhea that had not improved under treatment in outpatient clinics. Injections of isotonic solution of sodium chloride with dextrose were given, and isotonic solution of three chlorides with 3 per cent dextrin maltose was administered by mouth. The diet consisted of either buttermilk with dextrin maltose or human milk. Only 2 patients received plasma, and the use of antidiarrheals was avoided. A total of 0.1 to 0.15 Gm of sulfadiazine per kilogram of body weight was given daily in four doses six hours apart. From observations on 20 children the author concludes that this drug is an efficacious aid in the treatment of infantile diarrhea.

Prophylactic Dilation for Strictures of Esophagus from Lye.—According to Crowe, corrosive burns of the esophagus constitute one of the most difficult problems in pediatric practice. He analyzes 57 cases of ingestion of caustic alkali. The first aid given is generally poor. Patients with early poisoning due to lye can be saved secondary stenosis of the esophagus by the use of Bokay prophylactic esophageal dilation. This treatment should be used for every patient who has swallowed alkali unless there is definite pharyngoscopic proof that the esophagus is undamaged. If the presence of oral burns or the conditions revealed by fluoroscopy or pharyngoscopy indicate that the esophagus has been damaged even slightly, an eyeless (Bokay) catheter size 10 to 30 (French) which has been filled with lead shot or mercury, tied off at the open end and wet with water or with lubricating jelly, should be gently passed down the child's esophagus and left in place for five minutes once daily, starting on the third day after the child swallows the lye or as near that time as possible. The catheter should not be forced but allowed to pass by weight of the shot or mercury contained in it. During the first few days the size of the catheter should be increased until difficulty is encountered in passing it. From the third to the tenth week the largest possible catheter should be passed once daily and kept in place for ten to thirty minutes. The catheter should be introduced twice a week for the next month and then once a week for at least three months; then the interval can be lengthened to suit the patient's condition. Only 13 of the patients were seen in a sufficiently early stage so that Bokay prophylactic therapy could be used. In the 9 patients for whom Bokay therapy was adequate no strictures of the esophagus occurred. In 4 children the treatment at home was not sufficiently prolonged and strictures developed, necessitating a second admission to the hospital for gastrostomy and bougienage. Strictures developed also in 44 children who did not have Bokay treatment. All the patients with strictures required one of the following types of treatment: (1) peroral esophagoscopic bougienage, (2) retrograde bougienage through an artificial gastric fistula or (3) peroral bougienage with a silk thread used as a guide, procedures which involve long hospitalization (an average of fifty-six days), inconvenience, expense and the possibility of death from surgical causes. Four of the 48 patients died.

Sulfonamides and Yellow Fever in Cultures.—Koprowski and Lennette cultivated the 17DD High substrain of yellow fever in tissue culture in the presence of maximal concentrations of sulfapyridine or sulfathiazole. No evidence was obtained that

either of these drugs interferes with the propagation of the virus. No changes in the infectivity of the virus for mice were noted after fifty passages in tissue culture medium containing sulfapyridine.

Sulfonamides in Yellow Fever of Mice and Chick Embryos.—Koprowski and Lemette found that sulfapyridine and sulfathiazole administered orally or parenterally and sodium sulfapyridine administered parenterally had no demonstrable prophylactic or therapeutic effect on mice infected with yellow fever virus. Sodium sulfapyridine administered by way of the chorioallantoic membrane had no effect on the course of the infection produced in the chick embryo inoculated on the membrane with virus prior to or after administration of the drug.

Tuberous Sclerosis.—According to Sachs and Shaskan tuberous sclerosis is a rare hereditary disease of ectodermal origin. Tuberous sclerosis, Recklinghausen's neurofibromatosis and trigeminal nevus with angioma of the brain are distinct types of neurocutaneous syndromes. Of the three, tuberous sclerosis presents the most clearest clinical, roentgenologic and pathologic picture. It is most frequently associated with mental retardation and epileptic seizures. The authors describe a case of tuberous sclerosis in a white soldier aged 32. The cardinal findings in this case with a history of epileptic seizures were adenoma sebaceum, fibromatous nodules on the forehead, scalp and back, pigmented hairy nevus of the lumbar area,

viteligo of the left thigh and back, phacomia of the retina, an "cotton ball" calcifications of the brain, right greater trochanter and fifth lumbar vertebra. The authors think that delay in the diagnosis of tuberculous sclerosis is probably due to the physician's unfamiliarity with the syndrome because of relative scarcity.

"Ring" Sequestrums as Complication of Fixed Skeletal Traction.—Truog points out that a complication which occurs not uncommonly with skeletal traction is the formation of "ring" sequestrum. He has observed 7 such cases at an orthopedic clinic. Six of the patients were treated with pins incorporated in plaster casts which extended from the toes to above the knees with about 15 degrees flexion at the knee. They then became ambulatory and were seen in the outpatient clinic. Five of these 6 patients had pins inserted through the upper tibial fragment and the calcaneus; one had a pin driven through the distal fragment as well as the proximal fragment. These 6 all had delayed union. The seventh patient was treated with the Kirschner wire extension. He had a fracture of the femur and humerus and of the tibia and fibula. Non-union developed in both the femur and the tibia necessitating bone grafts. Roentgenologists should give special attention to such cases, as the diagnosis will depend entirely on the roentgen examination. It is important to make the diagnosis as soon as possible so that the skeletal traction may be removed. Constant traction under these conditions may lead to extensive bone damage or to migration of the pin out of the bone into soft tissue, epiphyses or joints. The cause is probably pressure necrosis plus a low grade infection.

Clinical Observations with Isonipicaine.—Noth and his associates made observations on the effect of isonipicaine on 146 patients, 118 of whom were suffering pain severe enough to justify the use of one of the opiates. The customary dose was 100 mg. given orally or intramuscularly. The drug was administered in 123 instances of severe pain to 118 patients (5 patients had two types of pain). Complete relief was obtained in 79, partial relief in 29 and no relief in 15 instances. The onset of relief was from five to twenty minutes following intramuscular injection and from twenty to thirty minutes following oral administration. Its duration varied between one and six hours but was usually three or four hours. Relief was more often complete following intramuscular injection. The analgetic potency of isonipicaine in the dose employed was greater than that of 1 grain (0.06 Gm.) or more of codeine or combinations of codeine and acetylsalicylic acid. It was usually less than that of morphine in $\frac{1}{4}$ or $\frac{1}{2}$ grain (0.016 or 0.032 Gm.) doses. The sedative action of isonipicaine was studied in the group of 81 patients with pain and in 24 patients without pain. The group of patients with pain received, as a rule, only a few doses of isonipicaine. Its administration was followed by sleep in about 50 per cent, by mild sedation in about 30 per cent and by no noticeable sedative effect in about 20 per cent of instances. The hypnotic or sedative effects following repeated administration were not profound, a fact which was of advantage in the treatment of

patients with chronic painful diseases. Three of 4 patients suffering from status asthmaticus were benefited by isonipecaine. Side effects were noted by 40 of the 146 patients, but in only 7 was it necessary to stop the drug. Laboratory studies showed no changes which could be attributed to it. In 9 of 21 patients who had received isonipecaine for varying periods of time the withdrawal of the drug and the substitution of one of the opiates were followed by certain undesirable symptoms. Isonipecaine is an effective analgetic drug which is relatively nontoxic. It may possess addictive properties, but these are apparently not as severe as those of some of the opiates. Isonipecaine is capable of replacing these drugs for a great number of painful conditions.

Cauda Equina Compression Syndrome with Herniated Nucleus Pulposus.—French and Payne observed a number of instances in which the protrusions of nucleus pulposus were so extensive as to produce complete, or nearly complete, subarachnoid block with cauda equina compression. The resultant symptoms so closely simulate cauda equina tumors that in most of the early cases exploration was done for suspected neoplasms. The authors gained the impression that cauda equina compression occurs much more frequently as the result of herniated nucleus pulposus as of tumor. They present 8 cases of cauda equina compression due to herniated nucleus pulposus. These cases were proved by myelography and operation. The pathologic process was encountered at the third lumbar in 1 case, at the fourth lumbar in 4 cases and at the fifth lumbar in 3 cases. There is considerable similarity in the symptom complex presented by these patients. Their main complaints were pain in the back and both legs, numbness in the saddle area and/or both legs, weakness and sphincter disturbances. There is usually a long antecedent history of back pain followed by an acute episode of rapid progression of the symptoms. The predominant symptoms were weakness or atrophy in the gluteal region or both legs, sensory changes in both legs, multiple reflex changes and sphincter abnormalities. Narrowed interspace determined by x-ray was frequently present and of differential diagnostic importance when found. Increased spinal fluid protein was the rule. Myelography showed complete or nearly complete subarachnoid block in all cases. The difficulty in differentiating this clinical entity from cauda equina tumor preoperatively is apparent.

Nitrogen Loss After Gastrectomy.—Co Tui and his associates reported in a preliminary communication that patients convalescing from gastrectomy, when fed with a high caloric and high amino acid diet (nutramigen), were able to maintain a consistently positive nitrogen balance throughout the postoperative period, to register a rise in body weight and to achieve an early return of strength and a significantly shortened convalescence. This picture was in contrast to that of a similar group of postoperative patients under the classic postoperative ward regimen, who had a consistently negative nitrogen balance,

a loss of body weight, a longer period of postoperative debility and a more prolonged stay in bed. The authors now report the results of treating a group of 19 patients, 8 of whom were on routine ward regimen, 8 were fed high caloric and high amino acid mixture, and 3 were fed in sufficient quantities to maintain nitrogen equilibrium. Under the classic ward regimen there was a consistent nitrogen deficit and loss of weight and a prolonged stay in bed. Objective ergography also showed postoperative asthenia, which had not disappeared on the twelfth postoperative day. In those fed with high caloric and high amino acid mixtures there was a consistent nitrogen surplus, a steady gain in weight and a stay in bed of less than one-half that of the control series. The ergograph showed an early return of endurance. The principal cause of nitrogen loss in postgastrectomy convalescence was the starvation postoperative regimen. The nitrogen loss resulting from the gastric suction was considerable. It was correctable by feeding an early assimilable high amino acid mixture. A hyperalimentation regimen consisting of high caloric and high amino acid feeding postoperatively has been worked out and found practical and is recommended in gastrectomy in order to circumvent nitrogen loss, shorten convalescence and prevent postoperative asthenia.

Ménière's Syndrome.—According to recent studies, Ménière's syndrome is due to an acute increase of fluid within the internal ear, particularly within the endolymphatic canal of the inferior part of the internal ear. These changes are called "hydrolabyrinth" to emphasize the similarity to hydrocephalus. The symptoms of Ménière's syndrome are due to acute hydrolabyrinth, which may resolve without injury to the internal ear or may lead to fixed dilatation of the inferior part of the internal ear and gradual or acute destruction of the sensorial cells. The typical Ménière attack consists of tinnitus, diminution of hearing, labyrinthine vertigo and spontaneous nystagmus. Only vertigo of the type which can be produced by the usual clinical methods of examining the labyrinth should be considered as labyrinthine. Spontaneous nystagmus between Ménière attacks is not of labyrinthine origin; it indicates an organic disease in the posterior cranial fossa. If the attacks consist only of labyrinthine or only of cochlear symptoms, a definite diagnosis cannot be made. If there is a systemic, cerebral or aural cause the symptom complex is

called "symptomatic Ménière's syndrome." When no etiologic factor can be determined, the disease is designated "idiopathic Ménière's syndrome." The pathologic changes are apparently the same in the two cases. The metabolic theory of the causation of the disease is not supported by microscopic observation, by chemical examination of the blood or by treatment. The vascular theory is supported by microscopic observation of the human ear as well as by experiment and explains the pathologic picture of the idiopathic as well as the symptomatic Ménière's syndrome. Most frequently the angioneurotic disturbances within the internal ear are due to arteriosclerosis of the brain. Various types of leukemia, syphilis, influenza, malaria, virus infection and particularly focal infection may cause the symptomatic Ménière's syndrome. Allergy is occasionally but not frequently a cause. A chronic adhesive process of the tympanic cavity frequently causes symptomatic Ménière's syndrome. When Ménière's syndrome is symptomatic, the etiologic disease should be treated. Treatment of the idiopathic type of Ménière's disease is difficult. Atkinson has recommended nicotinic acid on the ground that it is a vasodilator. The author employs symptomatic treatment, which is not always successful. Surgical treatment is justified only if the diagnosis of Ménière's syndrome is certain, if conservative measures have been exhausted and if the disease is progressive on one side while the other ear is normal.

Infantile Toxoplasmosis.—The number of reported cases of human toxoplasmosis, according to Zuelzer, totals 32. He reports 3 new cases. The first patient was a white boy who died on the third day of hospitalization when 11 days old. The second patient was a Negro infant, 1 of identical twin boys, who died when 1 month old. Complete necropsy reports are given of these 2 patients. The third patient, the identical twin brother of the second patient, is alive and has been under observation from birth to the present age of 7 months. Although in infants toxoplasmosis has a predilection for the central nervous system, the infection passes through a generalized stage in which many organs may be involved. The relative effect of toxoplasmosis on the central nervous system is magnified in later stages by the permanent character of the residual lesions, owing to the inability of nerve cells to regenerate, while lesions in other organs may heal with little or no residue. The disease may produce variable combinations of clinical and pathologic abnormalities. The parasites of toxoplasmosis invade tissue cells, in which they multiply, causing gradual loss of the characteristic cell structure and producing the appearance of cysts. The intracellular aggregate of toxoplasmas does not seem to produce a reaction in the tissue as long as the membrane of the host cell remains intact. Single parasites set free by rupture of a host cell or on their way from vessels to cells produce an inflammatory response. An equilibrium between host tissues and parasites may be established, leading to persistence of intact intracellular aggregates of toxoplasmas in normal tissues. The demonstration of the disease in twins, together with the presence of neutralizing antibodies in the maternal serum and the chronic character of most of the lesions observed in the twin who died of the disease at the age of 1 month, constitutes new evidence for the occurrence of prenatal infections with toxoplasma. One patient dying at the age of 11 days had an acute generalized toxoplasmic infection. Lesions were found in many organs,

among these the testicles, the pancreas and the kidneys, in which the infection has not been reported until now. The renal lesion consisted of focal glomerulonephritis. Generally the changes resembled those in acute toxoplasmosis of adults. The absence of demonstrable antibodies in the maternal serum indicates that the infection in this infant was acquired after birth and suggests that even early infantile toxoplasmosis is not always necessarily congenital. The clinical onset of the disease in the first few weeks of life is not in itself adequate proof of its prenatal inception. In the twins icterus accompanied the toxoplasmic infection. Icterus does not seem to be a common feature of the disease. Among 21 previously reported cases this symptom was present in only 3 instances. Analysis of the character of the icterus in the twins and of the underlying changes in the liver in the one who died does not support a causal relation to the toxoplasmic infection. Hepatosplenomegaly and extramedullary hemopoiesis in the spleen, the liver and other organs are genuine manifestations of toxoplasmosis of newborn and young infants.

Tantalum in Repair of Traumatic Cranial Defects.—Reeves states that, until the more recent use of vitallium and tantalum, materials other than autogenic bone grafts for the repair of cranial defects had been generally discredited. Tantalum is a bluish white metal, which has proved a satisfactory alloplastic material for the repair of peripheral nerves and cranial defects. The tantalum plates retain their original luster and show no signs of corrosion. No inflammatory reaction leading to extrusion or necessitating removal of the plates occurs. Because of its malleability the flat tantalum sheet can be cut to fit the defect with tin shears or heavy surgical scissors and then hammered or bent to the desired contour. By means of preoperative impressions, molds and models the tantalum sheet can be contoured accurately to fit the cranial defect and still be adjusted at the operating table. The accurately fitted plate is fastened to the bone with tantalum wire through perforations made along the edge of the plate. In the past year tantalum wire and foil have been used increasingly in the repair of peripheral nerves and the plates for the closure of large and difficult defects with very satisfactory results. The author describes 2 cases which illustrate the value of tantalum in the repair of cranial defects.

Heartburn.—Alvarez summarizes the results of questioning 123 persons with heartburn. The sensation consists of a burning and sometimes painful or rending distress, which begins usually under the lower end of the sternum and sometimes runs up as far as the pharynx. It tends to come in spells, and there are many curious and inexplicable features about its comings and goings. It does not appear to be due to any known organic disease of the digestive tract. At least 17 of the patients had or had had ulcer, but, curiously, when the ulcer was active and they had hunger pain they were free from heartburn. The symptom, therefore, did not seem to be produced by the ulcer. Heredity is sometimes a factor. Seventy-three per cent of the patients were men. Many of the patients suffered with regurgitation and belching, and these symptoms were occasionally associated with the heartburn, apparently only when the esophageal mucosa had been sensitized. When the esophagus was normal, regurgitation of acid gastric contents did not cause burning. Immediate causes of heartburn are eating too fast or too much or eating certain foods such as fats, coffee, onions, seasonings, radishes, tomato, orange, egg, cucumber, chocolate, peppers and cabbage. Alcohol and tobacco can be important factors, as can be emotion. Lying down or bending or exercising may bring on heartburn. The degree of acidity of the gastric contents is apparently not important, and heartburn can trouble persons with achlorhydria even to histamine. Three of the patients studied had cancer of the stomach. Sodium bicarbonate commonly gives relief, partly through neutralizing acid in the

esophagus and the stomach and partly by causing waves of reverse peristalsis to run out and stop coming. The evidence obtained in this study fits with that obtained by experimenters and suggests that heartburn is due largely to regurgitation into a sensitized esophagus and partly to reverse waves of peristalsis coming up from the stomach.

Deaths from Asthma.—Rackemann reviews the records of 82 patients who died because of asthma. Most of these deaths occurred in persons whose asthma began after the age of 45, although typical symptoms and pathologic manifestations can also occur in younger persons. Death from asthma is caused by the development of plugs of tough, sticky mucus which obstruct the bronchi and lead to suffocation. The pathologic picture is typical; it is characterized by voluminous, distended lungs of bluish gray, the cut section of which shows all the bronchi, especially those of medium and small size, occluded by plugs. The author presents one chart which shows in graphic form the mode of death and the pathologic changes in 50 of the author's patients who died with asthma as the presenting symptom. Of these, 27 presented pathologic features which he regards as typical of asthma. Another chart shows 55 cases found in the literature which meet the requirements, namely (a) a clinical history and a mode of death characteristic of asthma, (b) a necropsy showing voluminous lungs and bronchial plugs and (c) a necropsy showing no gross evidence of other causes of death.

Patch Tests in Poison Ivy Dermatitis.—Keil studied 72 cases, of which 40 were probable instances of dermatitis due to poison ivy, 26 of dermatitis venenata of various other causes, mainly plants, and 6 of doubtful instances of poison ivy. With the exception of the second subgroup, all of the patients showed positive reactions to an extract of poison ivy. The cases were carefully selected, so that the incidence of 64 per cent positive reactions to rhus extract was probably higher than the figures for normal subjects. These studies support the generally accepted opinions on the uses and limitations of the patch test in relation to poison ivy dermatitis: a positive patch test with a potent rhus extract does not prove the presence of dermatitis due to poison ivy but simply indicates sensitization to the plant. The diagnostic value of the test is depreciated by the high incidence of positive reactions in the normal adult population. A negative patch test eliminates past and present hypersensitivity to Rhus toxicodendron; on this point rests the chief value of the test in differential diagnosis of dermatitis due to poison ivy. The quantitative patch test is an important method of checking the value of treatment in this disease. A positive patch test does not necessarily mean that the patient has had clinical dermatitis from poison ivy or will acquire it under ordinary conditions of exposure. The relation between the results obtained with the patch test and the acquisition of clinical disease depends probably on quantitative factors involving the

degree of hypersensitiveness and the severity of exposure. Those showing positive patch tests are more apt to acquire a dermatitis from contact with rhus than those with negative patch tests. The value of the test in experimental studies cannot be overstressed. There is no apparent biologic relation between hypersensitiveness to poison ivy and that to fresh turpentine of various types or to alpha and beta pinene. Group reactions may be encountered with old specimens of turpentine, probably because of an increase in the phenolic fraction of turpentine. Evidence of a group relation between the active ingredient in poison ivy and pyrethrum or ragweed oil was not found. Evidence is presented to show, in substantiation of the work of Landsteiner and Jacobs in guinea pigs, that, in man, 3-geranyl catechol is biologically related to the active principle in poison ivy. Hypersensitiveness to 3-geranyl catechol seems to be dependent on the unsaturated geranyl group in combination with the catechol configuration.

Penicillin Allergy.—Feinberg points out that reactions to penicillin, mainly in the form of urticaria, have appeared in 5.7 per cent of patients receiving the substance. The reactions did not resemble the classic and severe allergic reactions which would be likely to follow the injection of an allergen to which the person had been naturally sensitive. Ten patients who were clinically mold sensitive and who gave positive reactions with extracts of various *Penicillia* were given skin tests with two batches of penicillin. Reactions were negative in all cases. Apparently *Penicillium* sensitive persons are safe from allergic reactions to penicillin. The possibility of allergic reactions cannot be totally ignored in view of the fact that the original source of penicillin is a potent antigen and that at times some of the antigen may be a final contaminant. It is suggested that as an added safeguard every batch of commercial penicillin be tested on known *Penicillium* sensitive persons. The author tested a more recently prepared penicillin of higher potency. This preparation could be tolerated by an average *Penicillium* sensitive patient in doses of at least 500,000 units.

Immediate Free Full Thickness Skin Graft for Traumatic Amputation of Finger.—McCarroll shows that the use of punch presses, trim machines, loading machines and numerous other automatic mechanical units by personnel often new and inexperienced in their operation is the factor responsible for the increasing role which traumatic amputation of fingers now plays in the field of traumatic surgery. Most of these injuries occur in the distal phalanx and result in a guillotine type of amputation, including all the soft tissue pad at the finger tip,

a part or all of the nail and part of the bone. The amputation in all cases in this series of 45 cases occurred through the distal phalanx. These patients were treated by immediate application of a free full thickness graft. Of these 45 cases, 43 have shown complete takes of the grafts. Each presented a smooth, well rounded finger tip, soft, nonadherent, nonsensitive and satisfactory in appearance; all the patients have been able to return to their former occupation. They have been able to work during the period of postoperative care, since only the involved finger was incorporated in a dressing. The remaining 2 cases are classified as failures with loss of the graft, although in neither instance was the graft a hundred per cent loss. Each retained enough of the graft to aid in filling in the defect and in decreasing the period of disability, although there was an increased amount of scarring over the finger tip, which was adherent to the underlying structures. Immediate application of free full thickness skin grafts should be considered as the procedure of first choice in the management of traumatic amputation of the finger.

Bone Drilling in Delayed Union of Fractures.—Pusitz and Davis say that bone drilling is not a method of choice in the treatment of definite nonunion; it is intended for the treatment of delayed union. Differentiation between delayed and nonunion involves time and roentgenographic studies. A delayed union may be still present at the end of ten months, whereas nonunion may be present at the end of ten weeks. There are three essential types of nonunion: (1) typical pseudarthrosis with sclerosis of the ends of the fragments, (2) fibrous union with osteoporosis of the fragments and (3) fibrous union with atrophy of disuse. In delayed union, although there may be no discernible callus, there is no sclerosis of the ends of the fragments. If there is absolutely no evidence of callus formation at the end of four to six months, delayed union may be considered to be present. A large number, probably the majority, of delayed unions will ultimately unite. This may take eight months or eighteen months, and a proportion of these delayed unions will resolve themselves into nonunions. Delayed union is the primary indication for bone drilling. It should be performed within a four to six months period. The dissection should be minimal. A series of thirty to fifty holes are drilled. After the bone has been properly drilled, simple closure is effected. The part is then properly immobilized, as after a fresh fracture. A well fitting, nonpadded plaster of paris cast is applied, to which a walking caliper is added after a week or ten days. The authors review 25 consecutive cases in which bone drilling was done. All cases except 1 showed bony union both clinically and roentgenographically. The average duration for the development of union after drilling was eight weeks. The shortest period was three weeks, and the longest was five months. The patients were up and around in a walking cast a week or ten days after operation. There were no postoperative infections.

Neurohistologic Findings in Experimental Electric Shock Treatment.—Winkelman and Moore subjected cats to electrocerebral shock, utilizing the faradic current of Berkwitz or the Cerletti-Dini type of house current. The experiments were conducted in close imitation to human electroshock therapy, and to 2 animals excessive doses were given intentionally. The nutritional aspects of the animals were carefully controlled. Microscopic studies of the brains and cords revealed no morphologic changes in animals receiving convulsive doses analogous to those given to human beings. In the 2 animals given excessive electric shock doses, one small area of pericapillary hemorrhage was seen in 1 and congestion of the smaller vasculature was observed in the other. In no case were subarachnoid hemorrhages or diffuse or extensive intracerebral hemorrhages encountered. While their studies indicate that permanent morphologic changes do not result from electrocerebral shock per se, they feel that intracellular biochemical changes do take place by virtue of the passage of the current and the resultant convulsion. These undemonstrable changes explain the clinical improvement in some patients. They gained the impression that in a large series of human cases in which a prolonged series of shocks was accompanied by a rise in blood pressure this was not attributable to cardiovascular-renal change but rather to changes within the autonomic nerve cells of the subthalamic nuclei.

Pathologic Aspects of Embolic or Metastatic Encephalitis.—Alpers and Gaskill, in their studies of 17 cases of embolic encephalitis, found that the heart valves are most frequently the source of metastatic encephalitis, particularly in cases of subacute bacterial endocarditis. Acute endocarditis of other types, pulmonary disease and foci involving other organs may give rise to this form of encephalitis. Clinical manifestations indicating brain involvement, particularly in endocarditis, may usher in the disease; they may be terminal or may occur anywhere along its course. The brain may contain few or numerous areas of encephalitis. These may be found anywhere in the cerebral hemispheres, brain stem or basal ganglia. Microscopically, brains so afflicted show a proliferative endarteritis which tends to be quite generalized, areas of perivascular infiltration with leukocytes, minute leukocytic nodules which are essentially miliary abscesses and in some instances areas of petechial and perivascular hemorrhage. Subarachnoid, cerebral or ventricular hemorrhage may be found as well as meningitis. The foci of metastatic encephalitis are probably blood borne and are probably carried by means of the system of paravertebral veins described by Batson.

Histopathologic Changes Following DDT Administration.—Nelson and his collaborators made microscopic studies on 117 animals of 9 different species after the administration of 1, 1, 1 trichloro-2, 2, 2 diparaphenyl-ethane, an insecticide which is generally designated as DDT. The substance was administered by intubation, by stomach tube or by admixture in the diet and in doses varying from those fatal in a few days to those causing no perceptible lesions after several months. The animals included rabbits, rats, guinea pigs, mice, chicks, dogs, cows, sheep and a horse. Although there were wide variations in sensitivity to the compound among the different animals of a given species, the lesions caused were quite consistent throughout the different species. On the higher dosage levels, with the animals surviving for one to several weeks, there resulted a moderate degree of central necrosis of the liver or, with the

longer periods of survival, a combination of central necrosis and reparative hypertrophy which can be labeled as a moderate subacute degeneration of the liver. The thyroid often showed moderate colloid depletion, less often epithelial desquamation and rarely epithelial hyperplasia. Slight to moderate focal necrosis of voluntary muscles occurred in about 20 per cent of animals on the higher dosage levels. Rabbits showed certain lesions not seen in the other species, a focal necrosis of the gallbladder and an increased incidence of the "spontaneous" types of encephalitis and nephritis. Dermatitis in immunized animals was mild throughout, except that rabbits on the highest doses showed slight focal necrosis of the epidermis. For a given dosage level of DDT, chickens and guinea pigs showed fewer microscopic lesions than did the other species. A special effort was made to determine nerve cell changes in the brain and spinal cord of animals with tremors. With routine fixation and staining (formaldehyde and Orth's; hematoxylin-eosin) no changes could be seen that were not present in controls similarly and concurrently fixed and stained. Rare myocardial and adrenal lesions may be of significance. DDT caused insignificant or no effects on bone marrow, bone, testis, pancreas and spleen. Renal lesions were slight and infrequent. Because of the tremors of long duration produced by it, DDT would appear to be a promising experimental agent for the neurophysiologist.

Cerebral Glioma in Siblings.—Riese and his associates state that the only "glioma" in which a familial tendency has been established is the glioma of the retina. Only occasionally has the familial occurrence of a true glioma been mentioned in the literature. They describe the clinical picture and the histopathologic type of 2 cases of cerebral glioma which occurred in 2 members of the same family (brother and sister). In both the growth developed in adult life, at the age of 39 in the sister and of 50 in the brother. In both cases the duration of the clinical history was two months. In the brother the tumor was a striothalamic growth; in the sister an involvement of similar regions was probable, although the tumor also involved the cortex. The histogenic type of the tumor was identical in the two instances; it was a glioblastoma multiforme. The sister also had a carcinoma of the left lung and uterine leiomyomas. The authors think that the fact that this woman did not develop a brain tumor of the same type of neoplasm which was present in the lung, but instead a primary glioma, is indicative of an intrinsic tendency to develop glioma. The authors do not think that pure coincidence would be satisfactory in explaining the occurrence of the identical type of brain neoplasm in siblings and suggest further investigations of the frequency of brain tumor in siblings and of the combination of primary brain tumor with primary tumors of other distant organs in the same person.

Myocardial Infarction in Congenital Dextrocardia.—Geeslin and Tyler present the history of an officer, aged 43, who complained of substernal "twisting" pain radiating into both shoulders and arms for the preceding four days. The presence of dextrocardia with situs inversus was established by physical examination, roentgenographic visualization of the transposed heart, stomach, liver and gallbladder and the mirror image inversion of lead I in the electrocardiograms in 1936 and 1943. Coronary occlusion was suspected from the history. The

changes in leads 1, 2 and 4 of the serial electrocardiograms were diagnostic of an anteroapical myocardial infarction. In congenital dextrocardia the conductive system of the heart is transposed as well as the chambers and, since the left arm is nearer the right auricle in contrast to the normally placed heart in which the right arm is closer to the right auricle, a total inversion of lead 1 and transposition of leads 2 and 3 is produced. The use of mirror image leads to study the "mirror image" heart is a logical procedure, and their use to study heart disease in the presence of dextrocardia has been reported previously. The use of the mirror image technic is particularly important for the precordial leads. To place the precordial electrode on the left chest when a dextrocardia is present must fail to elicit a fair proportion of the available cardiac current deflections and offer the confused possibility not only of deflection reversals but of change in contour shape.

Purpura of Henoch Simulating "Surgical Abdomen."—Bisson and David report the history of a child, aged 11, who fifteen days previously had had profuse sanguinolent vomiting. Sippy treatment was given for a week, but when at the end of this period a boiled egg was given another attack of sanguinolent vomiting occurred. At this time it was noted that the patient had petechiae on his feet, arms and buttocks. There was excruciating pain in the epigastric region. The child was stuporous, its temperature was 99.4 F. and the pulse rate was 88. The stupor and vomiting persisted and the stools became increasingly bloody. On the sixth day the child became doubled up with abdominal pain, refused all food and vomited repeatedly; the purpuric spots reappeared in large numbers on the extremities and the abdomen. An abdominal surgical emergency was thought of such as a typhic perforation, a Meckel diverticulum, intestinal invagination, acute pancreatitis or rupture of the appendix. On the following day the child suddenly was much improved and was free from abdominal pain, but the cutaneous spots persisted. The purpura was unusual because platelets and the bleeding time were normal. Schönlein's or rheumatic purpura is characterized by the predominance of articular symptoms, while Henoch's purpura is characterized by abdominal symptoms. Henoch's purpura should be defined as an allergic purpura with abdominal symptoms. In 95 per cent of cases of Henoch's purpura useless surgical interventions such as appendectomy, gastrectomy or cholecystectomy have been done. The treatment of Henoch's purpura is still largely empirical. It includes epinephrine to counteract the abdominal pain; vitamin P to regulate the permeability of the vessels and search for alimentary allergy and desensitization. This patient was found to be sensitive to crab meat and lima beans.

Penicillin in Battle Casualties.—Jeffrey and Thomson state that the War Office formed in September 1943 a "Penicillin Control Unit." Supplies of penicillin were flown to Italy regularly. The drug was distributed among eighty operating centers. The calcium penicillin was mixed with sulfathiazole in the strength of 5,000 units of penicillin per gram of sulfathiazole. This made a satisfactory powder, which, along with an efficient insufflator, was distributed among the forward operating centers. Most of the sodium salt was sent to base hospitals to give adequate courses of penicillin systemically. The forward units were given small stocks of sodium penicillin for use in gas gangrene and penetrating chest wounds. The transfusion officer and his orderlies were entrusted with the systemic administration; 15,000 units in 3 cc. doses was injected at three hour intervals. Occasionally the administration was by continuous intravenous drip. The intramuscular route proved more satisfactory. The technique of penicillin administration in secondary suture became standardized (1) for superficial wounds, if clean—a single insufflation of penicillin-sulfathiazole powder and suture; (2) for dirty superficial wounds—preliminary insufflations once daily for two days, then suture over a third insufflation; (3) for sinuses, and perforating wounds where the powder could not reach—suture with fine rubber tubes and instillations of 3 cc. (250 units per cubic centimeter) down each tube daily for four days. In all three types practically no excision was done except to freshen the skin edge and remove a loose tag. The powder was at a strength of 5,000 units per gram but latterly equally good results were obtained at base hospitals using 2,000 units per gram. In empyema systemic treatment with penicillin is not enough. In severe fractures the course of penicillin extended over five to ten days (500,000 to 1,000,000 units): 15,000 units was given three hourly by intramuscular injection. Infected amputation stumps healed fairly well when treated by means of tubes and instillations, but better results were obtained with a systemic course of penicillin. Encouraging results were obtained in gas gangrene; in addition to radical surgery and gas gangrene antiserum, penicillin was given systemically. It was not felt that there was a special indication for penicillin in penetrating abdominal wounds, for it seemed that the deaths were due to physiologic reasons rather than to sepsis. Penicillin-sulfathiazole powder was insufflated into surface wounds and into the depths of the brain. In brain

abscesses tubes and instillations formed the method of choice. With the use of penicillin-sulfathiazole powder many face wounds have had primary suture. Satisfactory results were obtained in cases of corneal ulcers and abrasions and conjunctivitis by two hourly drops of sodium penicillin, 1,000 units per cubic centimeter of distilled water. Penicillin-sulfathiazole powder insufflated on to the burned area and covered with tulle gras proved an excellent dressing for burns.

*Penicillin and Smallpox: Report of 4 Cases. W. D. Jeans, J. S. Jeffrey and K. Gunders.—p. 44.

Toxic Reaction to Thiourea.—St. Johnston states that, of 7 patients with thyrotoxicosis treated with thiourea, 3 developed toxic reactions. Pyrexia of 101 to 104 F. occurring eight to ten days after administering thiourea, with palpable enlargement of the spleen, a fall in the white blood cell count with monocytosis and a maculopapular eruption, was present in all 3 cases and appeared to be due to the thiourea. The 3 cases were remarkably similar. All symptoms and signs disappeared when the drug was withdrawn, to reappear in the first case when it was readministered.

Penicillin and Smallpox.—According to Jeans and his co-workers 37 patients with smallpox were admitted to a hospital in Italy during the spring of 1943. Two men soon died, covered with pustules. Four other men were critically ill and death seemed likely. They were covered from head to foot with vesicles which were becoming pustular and in places confluent. Throat and buccal mucous membranes were pustular and ulcerated. All 4 patients had had a course of sulfathiazole orally early in illness. Cultures from the pustules thereafter showed *Staphylococcus aureus* in abundance. The patients were then given sodium penicillin, 15,000 units intramuscularly every three hours, for three to four days (average 400,000 units). In the 3 that recovered there was a pronounced improvement within twenty-four hours. The quick drying of the pustules and subsequent minimal pock marking was quite striking. One of the patients who survived had never been vaccinated. The fatal case was one of confluent smallpox. The patient had been successfully vaccinated in the army in 1943 but never previously.

Proflavine Powder in Wounds.—Raven describes the effects of proflavine (2:8-diaminoacridine sulfate) in the treatment of wounds. All patients had received a chemotherapeutic drug before they reached the author. In the local treatment of wounds care is taken to ensure cleanliness of the skin surrounding the wound. Hair is shaved, purulent discharge is mopped

away and the skin is cleaned. If oil is present, ether soap is used; for ordinary contaminants soap and water suffices. A solution of 1 in 1,000 proflavine is then applied. Dead tissue is excised, avoiding sacrifice of good skin, and easily accessible foreign bodies are removed. Free drainage of the wound must be established. Next the wound is gently mopped with swabs soaked in a solution of proflavine so that a moderately dry cavity is obtained. Proflavine powder is carefully inserted into all parts of the wound, especially where there is a comminuted fracture of bone. The amount of proflavine powder used varies with the size of the wound. In most cases it has not exceeded 0.5 Gm. One layer of wide mesh gauze lightly impregnated with petrolatum is laid over the wound. In fractures, alignment of the bone fragments is secured and the part is immobilized in plaster over an adequate amount of cotton wool, which absorbs the wound discharge. If a joint is involved, it is immobilized in plaster in the correct position. Plaster is usually changed after about ten days. Proflavine was used not only in wounds involving bones and joints but also in suppurative lesions of the soft tissues and in burns. To ascertain its prophylactic value it has been applied to fresh wounds. The danger of overdosage is emphasized. In suppurating battle wounds the use of proflavine leads to satisfactory healing within a reasonable time and with a notable lack of scar tissue. Various infected lesions have been treated with a powder consisting of proflavine, sulfanilamide and ascorbic acid, and this combination has proved satisfactory for suppurating wounds, cellulitis and large chronic ulcers of the leg.

Endobronchial Perforation of Hilar Tuberculous Adenitis with Elimination of Lymph Node Sequestrums. P. Steiner and M. Geissberger.—p. 1232.

Actinomycosis of Lung Cured with a Sulfonamide.—Merkle reports the case of a farmer, aged 44, in whom actinomycosis started in carious teeth and involved the mandible with formation of fistulas and board hard infiltrations on the chin. A pleural empyema developed either as the result of the mandibular abscess invading the mediastinum, or the lung and pleura becoming involved by aspiration. In spite of the prolonged administration of large doses of potassium iodide and roentgen irradiation, the patient continued to have fever, leukocytosis, increased sedimentation reaction, suppurating fistulas of the mandible and fetid sputum containing *Actinomyces mycelium*. The patient was given 6 Gm. of n-dimethylacryl sulfanilamide daily for a period of seventeen weeks. This resulted in a cure. The patient has now remained well for four months. The total amount of 568 Gm. of the sulfonamide was well tolerated. In view of the great resistance of actinomycosis, the author regards it as unlikely that the chemotherapy acts directly on *Actinomyces*. Since *Actinomyces* is a saprophytic fungus and since actinomycoses with mixed infections are especially resistant, the author thinks that the administered sulfonamide preparation destroyed the favorable growth medium of *Actinomyces*.

*Therapy of Pleural Empyema. J. L. Gómez Pimienta.—p. 25.

Therapy of Pleural Empyema.—Gómez Pimienta classifies pleural empyema into tuberculous, septic and mixed types. Simple tuberculous empyema develops in patients with efficient artificial pneumothorax. Pleural drainage is here interdicted. Treatment consists in aspiration of the pleural cavity and lavage with 10 or 20 cc. of Lugol's solution in 1,000 cc. of isotonic solution of sodium chloride. Extrapleural thoracoplasty is indicated when the preservation of pneumothorax is necessary because of the severity of the tuberculous lesion. Tuberculous

empyema complicating active pulmonary tuberculosis develops in patients with inefficient artificial pneumothorax. The therapy consists in extrapleural thoracoplasty after emptying of the pleural cavity by aspiration and lavage. Mixed tuberculous and streptococcal or pneumococcal empyema is caused by pulmonary perforation or by exogenous contamination. Treatment consists in aspiration, administration of a sulfonamide, preliminary intercostal pleurotomy and extrapleural thoracoplasty. Septic empyema is treated with a sulfonamide, aspiration of pleural contents and subsequent pleural drainage. The latter is resorted to only after the tuberculous pulmonary lesion has become quiescent, as shown by the transformation of the pleural fluid to pus and after formation of mediastinal and pleural adhesions, which tend to immobilize the mediastinum and limit the size of the postoperative pneumothorax.

Costal Tuberculosis. H. A. Passalacqua, L. Farias and J. O. Gutiérrez.—p. 1058.

Dextrose in Pleuritic Effusion.—Garré and his collaborators state that the amount of dextrose in pleuritic effusion is of prognostic significance. They made quantitative determinations in pleuritic effusion of 27 patients. They found that the average amount of dextrose for each thousand cubic centimeters of fluid was 0.2702 Gm. in purulent pleurisy, less than 0.60 Gm. in serofibrinous pleurisy and more than 0.60 Gm. in nonpurulent pleurisy. In effusion with an amount of less than 0.60 Gm. of dextrose for each thousand cubic centimeters of the fluid, smears and cultures are positive for tubercle bacilli. In fluids containing an amount of more than 0.60 Gm. of dextrose for each thousand cubic centimeters of fluid, smears and cultures are negative for tubercle bacilli.

Sugar Tolerance Test in Comotio Cerebri.—Osterchrist points out that in the large majority of cases diagnosis of commotio cerebri is dependent on the statements of the injured or of witnesses, because there is no reliable method of clinical examination. Osterchrist investigated the sugar tolerance of 25 patients hospitalized with the diagnosis of commotio cerebri. These were not selected and clinically proved cases. The results of his tests are recorded in two tables. Table 1 records all cases that showed definitely pathologic curves, table 2 those with normal sugar tolerance curves. The sugar tolerance test permits differentiation of traumatically induced loss of consciousness from that caused by fainting, hysteria, coma and the like. Every traumatically induced loss of consciousness is accompanied by a temporary disturbance in the blood sugar regulation. This disturbance is frequently revealed in a pathologic increase in the fasting blood sugar and invariably in an abnormal course of a blood sugar tolerance test. Dextrose tolerance tests are valuable for the corroboration of the diagnosis of commotio cerebri. Cases with normal blood sugar tolerance curves are not true cases of commotio cerebri but are those of a traumatic shock. The author explains the concurrence of abnormal blood sugar levels with commotio cerebri as the result of a local traumatic impairment of the middle part of the hypothalamus with its sensitive functional centers.

Book Notices

Infections of the Peritoneum. By Bernhard Steinberg, M.D., Director of Toledo Hospital Institute of Medical Research. With a foreword by Frederick A. Collier, M.S., M.D., Professor of Surgery, University of Michigan Medical School, Ann Arbor. Cloth. Price, \$8. Pp. 455, with 45 illustrations. New York & London: Paul B. Hoeber, Inc., 1944.

Much has been written on peritonitis from many points of view by many authors. Dr. Steinberg's book is a comprehensive review of this voluminous material as well as the report of his intensive experimental and clinical work on the subject for eighteen years. There is more emphasis placed on the relation of basic sciences to the condition than in most publications dealing with peritonitis. Most of Dr. Steinberg's researches have dealt with etiology and pathogenesis, and his conceptions are deserving of widespread dissemination among the medical profession. Uniform understanding of the early stages of peritonitis and its development would result in earlier and better treatment and a corresponding reduction of mortality. The basic principles expounded so well by Steinberg are of great importance in the management of this condition. There has been a tendency toward slighting them and substituting indiscriminate chemotherapy. While chemotherapy is of great value, it cannot as yet, and may never, displace basic surgical principles. Steinberg brings this out well, and for this reason his contributions are not only important but timely. Though this book is perhaps too comprehensive to be read and digested by all "accelerated" medical students, it is worthy of being carefully read by all doctors who may come in contact with peritonitis.

Infectious Anemias Due to Bartonella and Related Red Cell Parasites. By David Weinman, Instructor in Comparative Pathology and Tropical Medicine, Schools of Medicine and Public Health, Harvard University, Boston. Transactions of the American Philosophical Society held at Philadelphia for Promoting Useful Knowledge. New Series—Volume XXXIII, Part III. Paper. Price, \$1.25. Pp. 243-350, with 2 illustrations. Philadelphia: American Philosophical Society, 1944.

This monograph is an intensive study of bartonella infections in man and animals with a digest of the literature (723 references). In man, Carrion's disease (Oroya fever and verruga peruana) as well as asymptomatic bartonellosis are encountered in Peru, Colombia and Ecuador. There is suggestive evidence that the area, which appears to correspond with the distribution of certain species of sandflies of the genus *Phlebotomus*, may be spreading. The bacteriology, symptomatology, blood changes, pathology and therapeutic measures are presented in detail and discussed. A chapter is devoted to the public health aspects of bartonellosis. As Dr. Tyzzer notes in the introduction, "the present monograph should serve as a reliable, modern and full source of information and reference; the South American literature, which is so difficult of access, being particularly well represented."

Technique in Trauma: Planned Timing in the Treatment of Wounds Including Burns. From the Montreal General Hospital and McGill University. By Fraser B. Gurd, M.D., C.M., and F. Douglas Ackman, M.D., C.M. In collaboration with John W. Gerie, M.D., C.M., Edward S. Mills, M.D., C.M., Joseph C. Pritchard, M.D., and Frederick Smith, M.D. Preface by John S. Lockwood, M.D., University of Pennsylvania, Philadelphia. With commentary by Ralph R. Fitzgerald, M.D., C.M., McGill University, Montreal. [Reprinted from the *Annals of Surgery* with additional Text.] Fabrikoid. Price, \$2. Pp. 68, with 20 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1942-1944.

This little volume is an attractively bound reprinting of three papers by the Montreal group which have appeared in the *Annals of Surgery* plus a foreword by John S. Lockwood and a commentary by Ralph R. Fitzgerald. The first two sections deal with the treatment of burns, and since the first was originally published in November 1942 it contains considerable material which is out of date. For example, it is recommended that tannic acid and silver nitrate be applied to large surface areas on the trunk or thighs. This method has fallen into disrepute, a fact which was recognized by the authors in the second paper, which appeared in December 1943, in which the exclusive use of a sulfathiazole emulsion was advised. The first paper mentions the use of a "burn tent" for the application of external heat. There is much evidence at hand that more harm than good is done by thus combating the so-called shock of

burns. The photograph of the tent in operation shows a patient apparently almost hermetically sealed in with a battery of heating lamps. It is doubtful that the conscious patient would tolerate such anoxic and uncomfortable conditions for long. On the other hand, appropriate stress is placed on the avoidance of unnecessary dressings and on the value of early dermatome skin grafting.

The third section considers the treatment of other types of injuries and infections. In a general way the authors favor the "let alone" methods of Orr and Trueta. There is generous use of the M. G. H. (sulfathiazole) emulsion for local implantation in wounds. There is no statistical proof of the necessity for the use of the sulfonamide. Anticipating this objection in his commentary, Fitzgerald states that controls are impossible in clinical surgery. This view is hardly tenable in the light of the published statistical studies of McIneny and the collaborating study units of the Committee on Medical Research in this country.

This monograph is a valuable record of the point of view of one group of surgeons interested in giving the best possible care to patients with various kinds of trauma. It is not, however, a handbook which the novice can use for a quick solution to all his problems in the treatment of the injured.

Fundamentals of Internal Medicine. By Wallace Mason Yater, A.B., M.D., M.S., Professor of Medicine and Director of the Department of Medicine, Georgetown University School of Medicine, Washington, D. C. Second edition. Fabrikoid. Price, \$10. Pp. 1,204, with 275 illustrations. New York & London: D. Appleton-Century Company, Inc., 1944.

This edition continues the policy set forth in the first, which appeared in 1939; it supplies in the briefest possible space the minimum of information necessary to deal with diagnosis and principles of treatment in clinical medicine exclusive of surgery. Subjects of special value to the internist in the armed forces have been added. Others, including primary atypical pneumonia, blood typing, hypoproteinemia, steatorrhea, sarcoidosis and coccidioidomycosis, have been revised or rewritten. A preliminary evaluation of the use of penicillin also has been included. There are fourteen contributors, including Dr. Yater. This is a true textbook rather than a reference book; the elimination of much material found in many similar publications unfits it to serve most reference purposes. Preparation of a book of this kind is now a colossal task. The appearance of a new edition at this time constitutes *prima facie* evidence of its popularity.

An Atlas of Anatomy in One Volume. By J. C. Belleau Grant, M.C., M.B., F.R.C.S., Professor of Anatomy in the University of Toronto. By Regions: Upper Limb, Abdomen, Perineum, Pelvis, and Lower Limb, Vertebrae and Vertebral Column, Thorax, Head and Neck. Reprinted 1944. Cloth. Price, \$10. Pp. 398, with 460 illustrations. Baltimore: William Wood & Company, [1944].

Designed to meet the needs of teachers and students and also those of physicians and surgeons, Grant provides in one volume a regional atlas that follows the method of dissection taught in American schools. It also should prove useful in clinical work. The structures of the human body are shown region by region: upper limb, abdomen, perineum, pelvis, lower limb, vertebrae and vertebral column, thorax, and head and neck. The drawings are by Mrs. Dorothy I. Chubb, a pupil of the late Max Broedel. To assure accuracy of the plates, each illustration is based on photographs of each specimen. A majority of the plates are colored, many of them in three, four or more colors. There is a detailed index providing a quick reference to the plates depicting any structure.

Accident Facts: 1944 Edition. Prepared by the Statistical Division, National Safety Council, Chicago. Paper. Price, 50 cents. Pp. 96, with illustrations. Chicago: National Safety Council, Inc., 1944.

The 1944 edition of Accident Facts presents in graphic form, and by means of tables and text, the important information concerning accidents in the United States during the calendar year 1943. This well organized booklet is indexed and one can find readily the total number of accidents by cause, by age group, by occupation and by geographic location and almost any other information on accidents which it is important to know. The National Safety Council deserves the full support of the medical profession in its efforts to reduce this leading cause of death and disability.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TRANSMISSION OF POLIOMYELITIS

To the Editor:—How is infantile paralysis transmitted? The town where I live (population 1,200) has had 2 cases within the last three weeks and the cry for effective prophylaxis is being sounded. According to articles available to me, there are two schools of thought. Dr. Stimson (The Journal July 10, 1943, p. 764) says that "it has not been proved that flies can carry enough [virus] to infect human beings." Maxcy and Howe, as quoted in the editorial Dec. 4, 1943, page 904, assume that "the disease would not attack children preponderantly, as is the case, were it transmitted primarily by the fly or any other insect." On the other hand, Rosenow, South and McCormack (Kentucky M. J. 35:437 [Sept.] 1937) and Trask, Paul and Melnick (J. Exper. Med. 77:531 [June] 1943) quoted in your editorial an Aug. 28, 1943, page 1250, accumulate data that a high percentage of flies, swarming around sewage-polluted water—is able to infect experimental animals. The reasoning of Maxcy and Howe seems to be fallacious, as (a) children are not exclusively attacked by poliomyelitis in our epidemic, (b) the relative immunity of adults may be easily explained by a possible previous abortive poliomyelitis infection and (c) the seasonal distribution of poliomyelitis seems to favor indirect, rather than direct, contact. In winter children are much more crowded, with more intimacy and more pharyngeal discharge; the first frost usually kills flies and the poliomyelitis epidemics; does it make little boys wash their hands more? The fact that both our cases appeared in families living near the sewer infected Housatonic River, swarming with flies, makes me think of a possibility of an insect vector.

George Vash, M.D., Hinsdale, Mass.

ANSWER:—The method of transmission of the virus of poliomyelitis has not yet been clearly demonstrated. Up to a few years ago the nasopharynx was accepted almost universally as the common port of entry as well as the port of exit of the virus of poliomyelitis. This theory enjoyed wide acceptance until three or four years ago, when the gastrointestinal port idea was reemphasized. The virus has been found consistently in the alimentary tract and stools of both patients and contacts. While a large body of circumstantial evidence supports the theory of direct contact from patient to patient, there is also the fact that virus has been recovered repeatedly from flies trapped in epidemic areas. However, the importance of the fly as a vector has not yet been clearly demonstrated. It is not possible in the present state of knowledge to say whether the contamination of the fly with virus is a result of the disease or a causal factor in it. The seasonal incidence of poliomyelitis epidemics, combined with the finding of virus in the human alimentary tract, stools, sewage and flies, lends weight to the contention that poliomyelitis is primarily an intestinal disease such as typhoid and dysentery. Not enough conclusive evidence has as yet been accumulated to permit a clear answer as to the usual mode of transmission.

SEBORRHEA OLEOSA

To the Editor:—A woman aged 27, married, without children, has an extremely oily scalp and oily face. She has no pimples and no blackheads. With the exception of a chronic sinus infection she is perfectly normal. She does have, however, attacks of hay fever. She has been checked thoroughly: blood, urine, heart, lungs, and all are within normal limits. The bowels are regular. I have tried many things but am unable to get rid of this oily condition. X-ray treatments were suggested to the patient, but she rebelled because of an unpleasant experience with x-ray burns. She will wash her hair, and within twelve hours the entire scalp will be greasy. Can you make any suggestions?

M.D., California.

ANSWER:—The case described is one of benign seborrhea oleosa, formerly called hyperhidrosis capitis (Jackson, G. T., and McMurtry, C. W.: Diseases of the Hair, Philadelphia, Lea & Febiger, 1912, p. 306) on the now discounted theory that the oil was a product of the sweat glands instead of the sebaceous glands.

Clinical investigations of the effect of large doses of vitamin A, vitamin D, niacin, pyridoxine or liver extract have produced evidence that each of these is effective in relief of some cases of acne vulgaris. Sex hormones, both male and female, have also been credited by some experimenters with good effects, by others with unfavorable effects. Such conflicts are also found in the research with vitamin A. One is forced to conclude that the causes of acne vulgaris are multiple and complicated. Some cases of acne rosacea also have been shown to respond to supplementation of the diet with large doses of riboflavin or of

pyridoxine or the combination of these two members of the B group. Other cases of acne rosacea do not respond to this treatment. The relationship between the various vitamins and their interaction with the hormones is complicated.

Sayer (Newer Concepts in the Etiology and Treatment of the Seborrheic Dermatoses, *Urol. & Cutan. Rev.* 46:719 [Nov.] 1942) reports good results in the seborrheic dermatoses from injections of crude liver extract 2 to 2.5 cc. once a week and a diet rich in vitamin B.

Local treatment may be helpful in the amelioration of the distressing features of the disease. It is presumed that hot packs to the face after soap and hot water cleansing have been tried as well as lotio alba. The latter can be used also on the scalp, if necessary in double strength (sulfurated potash 2 Gm., zinc sulfate 3 Gm. and bentonite lotion to make 30 cc.) applied to the scalp with a dropper after shaking the bottle. The bentonite lotion is made of 2.5 per cent of bentonite in rose water, allowed to stand several hours and then decanted to get rid of coarser particles (Fantus, Bernard, and Dyniewicz, H. A.: Cutaneous Preparations, *J. Am. Pharm. A.* 27:882, 1938). Daily application of this to the scalp results in drying of the hair as well as the stimulation of sulfur acting on the sebaceous apparatus.

In view of the objection to roentgen therapy, ultraviolet light may be used in dosage sufficient to cause a mild erythema.

ANTICOAGULANT TO FACILITATE INTRAVENOUS THERAPY

To the Editor:—Has an anticoagulant such as citrate or heparin been used to facilitate the slow administration intravenously of such solutions as penicillin by avoiding clotting in the needle or adjacent vein, without using enough anticoagulant to affect the general coagulation time of the blood? Can you cite references to the literature?

Dell Theodore Lundquist, M.D., Palo Alto, Calif.

ANSWER:—So far as can be determined, anticoagulants have not been used to facilitate the slow administration of fluids intravenously. The flow of the solution itself is usually enough to prevent coagulation at the tip of the needle. Penicillin solution, for example, may be administered by continuous intravenous drip by allowing as little as 2,000 cc. of fluid to flow into the vein over a period of twenty-four hours. This slow passage of fluid through the needle usually prevents clotting of blood. It would seem to be advisable to avoid the use of citrate or heparin, since comparatively large amounts would have to be used to prevent clotting, particularly in cases in which the infusion is kept up for more than twenty-four hours.

SUTURES FOR REPAIR OF TENDONS

To the Editor:—What size and type of suture are recommended for repair of tendons? What is the usual length of time of splinting and the optimal time at which to start passive and active movement of the involved tendons? I realize that each case is different but would appreciate general information.

R. M. Neseemann, M.D., Kewanee, Wis.

ANSWER:—No. 6 or No. 8 silk (Champion scale) is an excellent suture material. The exact size used depends on the thickness and strength of the tendon. It is impossible to say in a few words how long the part should be immobilized and when motion should be begun after tendon repair. The paper entitled "The Rate of Healing of Tendon" by Mason and Allen in the *Annals of Surgery* 113:424 (March) 1941 is one of the best discussions of the subject and offers the surgeon definite help in deciding on the best plan of treatment in an individual case.

PANCREATIC EXTRACTS FOR DERMATOLOGIC DISORDERS

To the Editor:—What available evidence is there that pancreatic tissue extract topically applied has any therapeutic effect on chronic eczema?

Walter Wilson, M.D., Bridgeport, Calif.

ANSWER:—Several authors have reported on the use of pancreatic tissue extract in cutaneous disorders. In all of these reports the material was given by injection. No report has been found in which the topical application of pancreatic extract was made.

PRESENT DAY PROCTOLOGY

CHAIRMAN'S ADDRESS

E. H. TERRELL, M.D.
RICHMOND, VA.

A cursory review of the history of medicine reveals that some interest has been manifested in proctology for many centuries. The etiology and pathology of the many diseases affecting the lower part of the bowel were not understood, and treatment was of the crudest and most unscientific sort until toward the end of the last century. It was not until about this time that any serious and orderly consideration of them was undertaken. Considerable impetus was given these studies by Dr. Joseph Mathews of Louisville, Ky., who has been considered the father of proctology. He was the first physician in the world to limit his practice to this field. Since his time there has been a continued and progressive advancement in the knowledge of these diseases.

Not unlike some other specialties, proctology has had to overcome certain prejudices, which were brought about largely because of indifference on the part of the profession or, probably to a greater extent, by incompetence. At any rate, this was for a long time a lucrative field for the advertising quack. During the latter part of the last century, and extending well into the early part of the present, the stigma of charlatanism was closely associated with proctology. There were, however, during this period a few ethical specialists who were doing good scientific work. Unlike the irregulars, they had nothing to conceal from either their fellow practitioners or their patients. For them there were no secret formulas, but whatever knowledge they possessed was given openly and freely. The more determined and enthusiastic of these in 1899 banded together in an organization which they called the American Proctologic Society, the purpose of which was the study and dissemination of knowledge pertaining to diseases of the rectum and colon. Since then great strides have been made in the understanding of the etiology of these various diseases; also greatly improved methods of diagnosis and treatment have been instituted. Now the skepticism toward proctology formerly held by the profession and some of the public has been, I believe, completely dissipated, and it holds as honorable a place as the other surgical specialties.

The proper limitations of the specialty have been much discussed but not determined definitely. There are some who confine their efforts to treatment of diseases within reach of the sigmoidoscope, probably 10 or 12 inches from the anus; others include surgery of the lower colon, colostomies and abdominoperineal resections for cancer or other conditions. Whether a proctologist shall attempt such a formidable operation as a resection is, of course, primarily dependent on his capabilities. If one has been well trained in this type of surgery he should by all means be encouraged to continue it, provided he has a sufficient number of these operations to maintain the proper technique. No operator wishes to shirk his duty or responsibility, but operations for cancer of the lower bowel, at best, carry with them much anxiety and oftentimes grief as well. When all has been said pro and con, each individual must be the judge of his own qualifications.

Proctology is one of the few specialties not overcrowded. There are many large and prosperous communities with no physician claiming any special knowledge in this line of work. Almost any one of these would support handsomely an energetic and well trained man. For a long time a gradually increasing interest has been shown in the study of proctology, although many would be students are handicapped because there is an insufficient number of places where proper training can be obtained. While at present nearly every medical school has a department in proctology for undergraduates, the daily schedule is so crowded that the student, at best, can obtain only a rudimentary knowledge of the rectum and its diseases. There are, of course, a few postgraduate institutions with courses in proctology, but these can accommodate only a limited number of students. At present the best opportunity for a young man to receive proper training is to become associated, if possible, with an older and well-established proctologist. Unfortunately, there are only a few such opportunities.

Since specialists in rectal diseases are relatively few, a large amount of this work is done by the general surgeon and much, not requiring surgery, by the general practitioner or internist. It is most gratifying to note that among our best surgeons and internists there is an increasing tendency toward more frequent proctoscopies. Many of these men become proficient in diagnosis, as any one can by study and close observation. It is unfortunate, however, that the impression still prevails, as it has for a long time in some quarters, that rectal surgery is simple and can be performed satisfactorily by the newest intern. Not only should the surgeon always

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

have in mind that his object is to remove existing pathologic conditions but he must so conduct the operation that, when healing is complete, there will be no impairment in the function of the parts. The accomplishment of these purposes usually requires a rather exacting technic, equal to that of most abdominal operations. I am confident that there are more unsatisfactory hemorrhoidectomies than appendectomies performed. In the hands of an experienced surgeon, however, a patient has every right to expect, when he submits to an ordinary rectal operation, that he will be completely relieved of symptoms and also that there will be no impairment of function of the parts. Of course, exceptions may occur in cancerous conditions and in some deep and extensive infections. I may add, however, that untoward results are by no means always due to a faulty operative technic. Oftentimes there are other causative factors, and chief among them is lack of proper after-care. Rectal wounds seem to require more attention than those of other parts of the body, and the conscientious surgeon gives them his personal attention unless he has a trained assistant to do this for him.

Often of great concern by the patient who contemplates a rectal operation is the possibility of an incontinence resulting. Loss of control is always to be deplored, of course, but there is little reason, for its occurrence except in rare instances. The most common cause of this in the past has been the almost universal custom of forcibly dilating the sphincter muscles as a preliminary step in all rectal operations. This procedure of "paralyzing the sphincters," an expression often employed, was deemed absolutely necessary, particularly if the sphincters were at all spastic. Whether stretching was done with the fingers or with instruments, the muscle fibers often were injured to such an extent that their tone and contractability were destroyed, allowing a leakage to liquid or soft stools. The best informed proctologists no longer dilate the anal canal during any operation unless a fibrous constriction is present.

The postoperative care of a fistula is as important as the operation itself, and not infrequently a failure to cure is due to inadequate attention to the wound. For a time there were some who advocated excision of fistulous tracts with immediate suture. Failure to secure primary union was so common that the method has been abandoned almost entirely. Now it is considered best to leave the tract open to heal by granulation. Until recent years it was thought necessary to keep such wounds tightly packed until healing was complete. This practice has been discarded. It was observed that continuous pressure of the gauze forced apart not only the wound edges but also any muscle fibers which may have been incised. In the healing of a tightly packed wound there will be deposited a wider and more extensive amount of fibrous tissue which, because of its rigidity, necessarily interferes with the normal closure of the sphincters. Incontinence following fistulectomy is more often due to excessive scar tissue than to incised muscles. Of course, adhesions between adjacent raw surfaces must not be allowed to take place, but if such wounds are otherwise left alone the resulting scar will be narrow and interfere little, if at all, with the normal function of the sphincters.

Formerly the so-called "rectal plug" was used regularly by many surgeons on the completion of every

rectal operation. This was left in position for several days, the purpose being, it was said, to keep the muscles dilated, prevent adhesions and furnish an avenue of escape for gases. Such a foreign body in the anal canal caused much pain, requiring regular doses of opium to control. Also, when used, retention of urine was a frequent complication. As far as I know, the plug is no longer employed.

The proper interpretation of symptoms and an avoidance of hasty conclusions are necessary in the practice of proctology. Unless one is constantly on the alert there are many possibilities of error. It will be disconcerting, to say the least, to find, shortly after performing a hemorrhoidectomy, that there is a malignant growth only a few inches away. Again, at other times, small symptomless hemorrhoids are removed for pain, bleeding or itching when the symptoms have an entirely different cause. Rarely will a false interpretation be placed on rectal symptoms if a proper and painstaking investigation is made. Errors in diagnosis in this region are usually inexcusable, for most of them are due to carelessness.

When a perirectal abscess is incised the physician, for his own protection if for no other reason, should inform the patient that such an abscess is the first stage of a fistula and that a chronic draining sinus is likely to ensue; also, in all probability, a removal of the sinus or fistula will be necessary before relief is obtained. Too often, if reports are true, attempts are made to cure these tracts by irrigation, cauterization or packing. Such treatment is time consuming and always disappointing.

Every one at all interested in proctology should be familiar with the work of Dr. George Thiele of Kansas City. His contribution, in my opinion, is the most valuable given in our field during the past decade. I refer to a paper read by him¹ in this section and published in THE JOURNAL about five years ago, in which he called attention to spasm of one or more of the deep pelvic muscles causing symptoms previously not satisfactorily explained. The muscles involved are the coccygeus, pyriformis or levator ani, and their spasticity usually may be detected by palpation. Symptoms associated with this condition are somewhat variable, most often a feeling of pressure in the rectum or a dull aching, neuralgic in character, which sometimes extends to the vagina. Systematic and regular massage of the affected muscles, as suggested by him, gives relief in most instances. We have been pleased to note that frequently an associated coccygodynia and low back ache disappear also after massage of these muscles. Apparently no cause for this spasticity has been determined.

Most proctologists are conservative and attempt operations of only the most minor nature in their offices. Surgery of any magnitude is best done in a hospital where suitable assistance is obtainable and conditions in every respect more favorable. I am confident that often too much is undertaken in the office, particularly by young men with limited experience. Only one or two uncontrollable hemorrhages will suffice to convince any one that there are distinct limitations to office surgery. On the contrary, however, the well trained proctologist treats many ailments satisfactorily.

1. Thiele, G. H., Coccygodynia and Pain in the Superior Gluteal Region, J A M A 109:1271 (Oct 16) 1937.

factorily in his office. Here, again, his knowledge of pathology usually will allow him to differentiate rather accurately whether a condition requires surgery or can be relieved by nonsurgical methods. There are borderline cases which treatment will benefit but not cure completely. In such instances surgery is advisable unless contraindicated because of age or physical disability.

The ambulatory treatment of hemorrhoids has become very popular in recent years. I fear that its limitations are not always understood. Only simple, uncomplicated, internal hemorrhoids are suitable for treatment by the electric needle or by injection of any one of the popular sclerosing agents. Surgery is indicated in all forms of hemorrhoids when associated with other diseases, as cryptitis, papillitis or fistula.

At present most surgeons employ the so-called ligature method in removing hemorrhoids. This seems altogether the most satisfactory and is followed by fewer complications than others. Some still use the clamp and cautery, although usually this causes more pain, and in healing there is deposited a greater amount of connective tissue; also secondary hemorrhages are more frequent. The Whitehead operation, very popular in some sections a few years ago, is almost obsolete now. Theoretically it was considered the perfect operation, but the end results in many instances were far from satisfactory.

Postoperative treatment in rectal surgery has changed materially in recent years. Unless there are unusual complications, soft diet is allowed the morning after operating. In forty-eight hours a bowel movement is secured by either a mild laxative or an enema, following which the patient is given general diet and is allowed out of bed *ad libitum*. Even within a few hours after operation he may be permitted to stand if there is difficulty in voiding. In allowing this no harm has been observed, but often retention and catheterization, always objectionable complications, may be avoided. Hot sitz baths and hot compresses add much to the comfort of the patient and are conducive to healing. Unless the operation has been extensive or an unusual one, the patient leaves the hospital in four to six days. He is requested to report to the office regularly every few days until healing is complete. At these visits any tendency to adhesions or bridging of the wounds is forestalled and excessive granulation tissue removed. Success or failure of operations on the rectum is more often dependent on the amount and nature of the after-care than is generally admitted.

Many surgeons have reported favorable results from topical applications of the sulfonamides to open postoperative wounds. It has been my experience that their use has not reduced noticeably the time of healing, and in no way have they seemed superior to the mild antiseptic wet dressings and sitz baths which have been employed for many years. These drugs, however, administered internally are most effective and indispensable in many deep seated infections. In addition, certain of them are more or less specific in many cases of ulcerative proctitis. All drugs of this class are dangerous and should not be prescribed indiscriminately. For myself, when I think they are indicated I prefer that they be administered by and under the close supervision of an internist or a gastroenterologist. The medi-

cal practitioner is better able to keep a close watch and detect in their incipience any untoward effects, should they arise. In fact, there should be a close cooperation between the gastroenterologist and the proctologist. There are innumerable occasions in which they may be of mutual benefit.

Most of us are more or less creatures of habit. We often prescribe remedies or employ methods handed down from one generation to another without consideration as to their merits. One in particular is the custom, in some localities at least, of prescribing ointments and suppositories containing opium for inflamed and painful conditions at or near the anal outlet. Few drugs are absorbed through the unbroken skin. Opium is not a local anesthetic and, when applied or inserted into the rectum, can relieve pain only after it is absorbed into the blood stream. A mild antiseptic wet dressing with a hot water bag over it is generally more effective than any ointment or suppository. Most of the popular ointments and suppositories owe their reputation to the fact that they are used generally in acute, self-limiting diseases.

The physician should discourage the indiscriminate use of laxatives. One is sometimes surprised how quickly a sluggish and inactive bowel will respond to simply a regulation of diet and habits, when the patient is fully cooperative. Frequently, however, some aid other than laxatives is necessary. For this purpose preparations containing seed taken in 1 to 2 teaspoon doses daily are very effectual in many instances. They seem not to have any of the detrimental effects of liquid petrolatum, which for many years has been used extensively in chronic constipation. Oil interferes with digestion, prevents proper assimilation of food and prevents absorption of certain vitamins. The taking of oil, except for a very limited time, should be discouraged.

Some physicians make it a rule to order a roentgenoscopy whenever cancer of the lower bowel is suspected. A tumor located in the ampulla of the rectum often is not diagnosed definitely by the x-rays. When the report is found to be inconclusive, a proctoscopy is requested. The procedure should be reversed. If a growth is located through the proctoscope a biopsy specimen will determine the diagnosis definitely. Then roentgenoscopy is generally not necessary.

We are passing through an era of great progress in medicine. Proctology has kept pace with all other progressive departments of medicine and probably is ahead of some. These accomplishments have been the result of contributions of many interested, hard working and observant individuals. We have by no means, however, reached the stage of perfection. That new ideas and improved methods will continue to be brought forth from time to time there is no reason to doubt; that is, while we remain free and independent agents. When, however, the practice of medicine becomes regimented, as is strongly advocated in certain quarters, most certainly progress will be at an end. Then medicine will be practiced carelessly and indifferently.

One cannot imagine that physicians of today will tolerate the dictatorship of a centralized group of selfish and autocratic politicians, whose chief interest is not that of their dear constituents, as they claim, but that of feathering their own political nests.

116 East Franklin Street.

CHRONIC GLOMERULONEPHRITIS AND THE NEPHROTIC SYNDROME

A FOLLOW-UP INVESTIGATION OF PATIENTS
TREATED WITH ACACIA

RAYMOND E. SMALLEY, M.D.

First Assistant in Medicine, Mayo Clinic
AND

MELVIN W. BINGER, M.D.

ROCHESTER, MINN.

"It is indeed an humiliating confession that although much attention has been directed to nephritis for nearly ten years—yet little or nothing has been done toward devising a method for permanent relief, when the disease has been confirmed; and no fixed plan has been laid down as affording a tolerable certainty of a cure in the more recent cases." Richard Bright¹ wrote the foregoing in 1836. In 1944 we still must confess that we cannot cure the patient who has this disease, but the plan of treatment² here to be described restores many of the patients to work and eases the sufferings of those who are bedfast.

Our purpose in this study was to ascertain the health of the patients and the status of the disease from which they suffered in the interval between the time of their first treatment at the Mayo Clinic and the time of the follow-up investigation. At the time of admission at the clinic the 109 patients selected for study had in common glomerulonephritis and the nephrotic syndrome, extensive and resistant edema, and they were treated with injections of a solution of acacia in the years 1937 to 1943 inclusive. By "nephrotic syndrome" is meant the clinical state characterized by albuminuria, the presence of edema and a decreased concentration of serum albumin. In addition, the concentration of blood cholesterol usually is elevated and not infrequently the basal metabolic rate is lowered. Two of the 109 patients, in addition, received diagnoses of Hodgkin's disease; 1 other patient had indeterminate edema and 1 chronic hepatitis. Of the 109 patients, 72 were alive and 25 were dead at the time of the follow-up investigation; we received no response concerning 12. Of the 72 patients known to be living, 27 were more than 40 years of age at the time when data for this report were gathered.

Glomerulonephritis with nephrotic tendencies is primarily a disease of children and young adults. Grouped according to decades of life, most of the patients were in their teens when the symptoms became evident and the next largest number were in the third decade of life. Three patients were less than 10 and 2 were more than 68 years of age. The exact age of the onset is difficult to determine because patients without extrarenal symptoms frequently do not go to a physician. It has been said³ that even now in the majority of instances the presence of Bright's disease remains unsuspected and that only a small proportion of all people with this disease ever lie on a postmortem table or even in a hospital bed. Most of our patients had had symptoms of renal disease for three to four

years when first seen at the clinic; in 5 of the cases the kidneys had been known to be involved longer than ten years and in 2 of them longer than eighteen years. Males seem to be more susceptible to the disease than females. In our series of 72 patients who could be followed up 39 were men and 33 women.

These patients complain chiefly of malaise and of discomfort from the edema. In a severe case the legs are so swollen that to walk is troublesome. Swelling of the genitalia may make urination difficult and painful; edema of the abdominal wall and ascites cause distention, impede respiration and cause slowing of gastric motility; pleural effusion causes dyspnea and may embarrass the circulation; edema of the stomach and intestine causes loss of appetite, indigestion, nausea, vomiting and intestinal irregularity; cerebral edema may cause headache, mental confusion, lethargy and possibly psychosis. All but 3 of the group of 109 patients had edema, varying from pitting edema at the ankles, sometimes extending upward to the knees or hips, to generalized anasarca with fluid in the body cavities. Forty-two patients had clinically demonstrable fluid in the pleural or peritoneal cavities.

Our plan of treatment is directed toward removing the edema and helping to restore the normal concentration of serum protein. Dietary aids consist in restriction of intake of sodium and protection of the normal concentration of serum protein. Patients are instructed to take either a salt free diet or one containing only the salt used in preparation of the food. Intake of fluids is limited to not more than 1 to 1½ quarts (approximately 1 to 1.5 liters) daily. The protein content of the diet is increased to between 75 and 125 Gm. daily because of the excessive proteinuria that is one feature of the nephrotic syndrome. There is no evidence that forced injection of protein produces a significant rise in the concentration of serum protein, although it may prevent progress of hypoproteinemia. Vitamins and iron may be used to supplement the diet. Potassium nitrate is used indefinitely in a dose of 3 Gm. three times daily. This diuretic drug has low toxicity, is easily administered and has the desired diuretic action. Administration of acacia is indicated when renal function is good, the concentration of serum protein is low and the edema does not respond readily to treatment in the hospital. The usual total dose is 90 Gm.; that is, a 6 per cent solution of pure acacia in 1,500 cc. of a 0.06 per cent solution of sodium chloride. One third of this quantity is given in each of three intravenous injections administered usually on alternate days. In the average case in which the intake of fluid is controlled, this quantity will give a concentration of approximately 2 Gm. of acacia per hundred cubic centimeters of blood serum. It fails to give this concentration or if clinical edema is still present, further injection can be given. Mercurial diuretic drugs may be more effective after administration of acacia than before.

The acacia is gradually eliminated from the blood. One year after the administration the average concentration is 100 mg. per hundred cubic centimeters of serum. Power⁴ has reported 25 mg. per hundred cubic centimeters being found in the serum three years after the last injection. The concentration of acacia in the blood serum of 1 patient who recently returned for reexamination six years after her last injection of acacia was 10 mg. per hundred cubic centimeters.

4. Power, M. H.; Keith, N. M., and Wakefield, E. G.: *The Persistence of Acacia in the Blood After Intravenous Injection of Acacia Solution*, *Am. J. Physiol.* **113**: 107 (Sept.) 1935.

She had received the average total dose of 90 Gm. of acacia. Twenty of the 25 patients who were dead at the time of the follow-up investigation had lost their edema when hospitalized at the clinic under treatment which included administration of acacia. Twelve⁴ of the 25 patients lived two years or longer after returning home. Five patients lived four years or longer. The listed causes of death were further manifestations of chronic Bright's disease, such as uremia, hypertension and cardiac failure in most of the cases; also acute appendicitis, mastoiditis, pancreatitis, septicemia and old age were reported.

We now propose to discuss certain manifestations of this disease, found at the initial examination and either at reexamination or at the time of the follow-up inquiry of the 72 living patients.

Of this number, at the time of the follow-up investigation 49 were doing a full day's work—substantial work as business executives, stenographers, farmers, housewives and students. One woman was teaching school in addition to caring for her house and family. Two patients were only slightly handicapped, 19 were working part time, at least half a day, and 2 were bed patients. One of the latter was a man 74 years of age.

Administration of acacia was instituted 103 times with reference to these 72 patients, and 342 separate injections were given. Most patients received 90 Gm. of acacia distributed in three injections; however, 1 patient has received nineteen injections, or 570 Gm., and 12 have received more than 200 Gm. No ill effects have been reported.

In 12 cases reactions occurred in the course of administration of the acacia. They consisted of coldness of the extremities, flushing of the face, chill, nausea, vomiting, dyspnea and urticaria. Two of these 12 patients had reactions two and three times, but all the patients were able to complete the necessary injections, including 1 patient with a proved allergy. In some instances epinephrine was given in the solution prophylactically to patients who had had one reaction, and this prevented recurrence.

Nephrotic edema may develop at any time during the course of the disease. One patient was relieved of clinical edema sixteen years after onset of the disease and 2 others twelve and eight years respectively after the disease began. Acacia was given to these 3 patients on one or two different occasions. All were working when this was written. Acacia was administered to these 72 patients at least two years, and to some of the patients seven years, before the time of this report. The mode of action of acacia is not certain, but it does facilitate excretion of sodium chloride and water.⁵ The value for blood chlorides was elevated on primary admission in most of the cases in which the value was determined. Once the excretion of sodium ion is initiated, edema fluid is restored to the circulation and then is eliminated by way of the kidneys. Under treatment, all 72 patients lost weight with the diuresis and with the decrease in edema. The average loss of weight was approximately 19 pounds (8.6 Kg.) per patient. Twelve patients lost 30 pounds (13.6 Kg.) or more and 3 lost 46, 55 and 60 pounds (20.9, 24.9 and 27.2 Kg.) respectively. On the average, 1 to 2 pounds (0.5 to 0.9 Kg.) is lost daily.

The normal concentration of serum proteins is 6 to 8 Gm. per hundred cubic centimeters⁷ and the normal albumin-globulin ratio $\frac{1.5 \text{ to } 3.0}{1}$. Among 38 patients reexamined after administration of acacia on a previous visit the value for total serum proteins of 30 was found to have increased. In addition the albumin-globulin ratio of 2 had become normal. Clinically, 15 patients of this group of 38 had had ascites or demonstrable pleural fluid in addition to the peripheral edema at the time of the first admission but not at reexamination. Also 33 of the 38 patients had no edema or minimal edema of the ankles only at the time of the last admission, while all of them had exhibited considerably more edema than this when first seen at the clinic.

What has just been said about edema, serum acacia and serum proteins is illustrated in the following report of a case:

A woman aged 60, who was admitted to the clinic Sept. 20, 1941, stated that for five years she had had frequency, nocturia and dysuria without chills, fever or colic. Six weeks before she came to the clinic, while on a trip and after she had waded in

a cold stream, a cold had developed and at that time the patient first had noticed swelling of her ankles and legs. This condition had progressed until her abdomen had begun to swell ten days before her admission.

On examination the legs were found to be decidedly edematous and the edema extended upward to include the sacral and lumbar regions. She had ascites as well as effusion in both sides of the thorax, as shown in the accompanying chart. She weighed 125 pounds (56.8 Kg.). The blood pressure was normal and results of examination of the ocular fundi were essentially negative. Urinalysis revealed a specific gravity of 1.019, albuminuria graded 4 and pus graded 1. The blood contained 26 mg. of urea per hundred cubic centimeters and 3.6 Gm. of serum proteins. The albumin-globulin ratio was $\frac{1.1}{1.0}$. An intravenous urogram revealed multiple vesical diverticula, one of which contained a stone. The vesical findings were thought to account for the local urinary symptoms. A diagnosis was made of chronic glomerulonephritis with nephrotic features, and vesical diverticula with stone.

The patient was in the hospital sixty-five days after her first admission. At once a diet was prescribed which was free of

salt, high in protein and high in calories and of which the quantity of fluid was controlled. As a diuretic measure, administration of potassium nitrate in a dose of 9 Gm. daily was started but had to be discontinued after four days because of nausea. On the patient's third day in the hospital abdominal paracentesis was performed, and 1,200 cc. of fluid was removed. On the sixth day in the hospital 500 cc. of clear fluid was aspirated from the right side of the thorax. On each of the third, fourth and fifth days in the hospital injections of 500 cc. of 6 per cent solution of acacia were given intravenously, in all 1,500 cc., containing 90 Gm. of acacia. On the day following the last injection the concentration of serum acacia was 1.97 Gm. per hundred cubic centimeters. On the patient's tenth day in the hospital her weight was 107 pounds (48.6 Kg.) and her condition was improved enough to warrant surgical treatment for the vesical diverticula and stone. The postoperative course was essentially uneventful but, because edema of the ankles and legs developed, a fourth intravenous injection of 500 cc. of 6 per cent solution of acacia was given in the fourth postoperative week.

Three months after the patient's dismissal from the surgical service she was readmitted to the hospital because of increasing edema. Examination revealed pitting edema of the legs, including the hips, and ascites was present although the thorax was clear. She weighed 110 pounds (50 Kg.). There was no change in urinary findings from those of her first admission or in the results of examination of the ocular fundi. The concentration of blood urea was 24 mg. per hundred cubic centimeters and that of serum proteins 3.2 Gm. per hundred cubic centimeters. The albumin-globulin ratio was $\frac{1.1}{1.0}$. The value for serum acacia was 0.33 Gm. per hundred cubic centimeters. The patient was in the hospital twelve days on her second admission. Her diet was controlled as before. Potassium nitrate 9 Gm. was given daily. On each of the fourth, sixth and eighth days in the hospital 500 cc. of 6 per cent solution of acacia was administered intravenously, 1,500 cc. in all. On the day following the last injection of acacia the value for serum acacia was 2.40 Gm. per hundred cubic centimeters. The patient's weight decreased to 94 pounds (42.7 Kg.) and clinically she was free from edema. She was dismissed to go home with a prescription for a controlled diet and was advised to take 9 Gm. of potassium nitrate daily.

The patient was seen at the clinic on her third admission, four and a half months following the second dismissal. She came because her husband insisted that she be reexamined. She had been doing her own housework and climbing fifteen stairs twice daily without difficulty. Examination revealed minimal edema at the ankles. She weighed 101 pounds (45.9 Kg.). Blood pressure was normal. Urinalysis revealed albuminuria graded 3. The concentration of blood urea was 26 mg. per hundred cubic centimeters. The concentration of serum proteins was 5.0 Gm. per hundred cubic centimeters and the albumin-globulin ratio $\frac{1.2}{1.0}$. The value for serum acacia was 0.83 Gm. per hundred cubic centimeters. The patient was dismissed to go home and was advised to continue with the same treatment. She wrote us recently that she was getting along well.

Values for blood cholesterol ranging from 129 to 1,190 mg. per hundred cubic centimeters were obtained at the time of first admission of 65 of the 72 patients who later responded to our questionnaire. In 60 of these cases the values were primarily in excess of what we considered the normal of 160 to 200 mg. per hundred cubic centimeters. The values in 47 cases fell between 216 and 595 mg. per hundred cubic centimeters. The 2 patients most seriously ill at the time of writing of this paper had values of 378 and 490 mg. per hundred cubic centimeters. The patients with respectively the very high and the very low values were working and well. When the patients were placed under dietary control, the values for blood cholesterol that had obtained on primary admission fell rapidly toward normal; that is, in 1 case in which the value on primary

admission was 595 mg. per hundred cubic centimeters the value became 282 mg. per hundred cubic centimeters eight days later. It was also interesting that in cases in which values for serum protein on primary admission were low frequently hypercholesterolemia was found, while in cases in which values for serum protein were more nearly normal on primary admission the values for blood cholesterol were low. Peters and Man' reported that in their series of 54 nephritic patients the hypercholesterolemia bore no consistent relation to any single phenomenon of the disease. They stated that hypercholesterolemia was encountered most frequently in the presence of edema and that it was most striking in cases in which there was the greatest deficiency of serum albumin. From these observations it would appear that the initial value for blood cholesterol has very little prognostic significance.

We used retention of blood urea as an index of renal function in place of the urea clearance test because of the poor urinary output of this group of patients. This value is obtained by multiplying the value for ure nitrogen by the factor 2.14. The normal value range between 15 and 40 mg. per hundred cubic centimeters. On their first admission 26 of the 72 patients gave evidence of some renal insufficiency, as shown by elevation of the concentration of blood urea. These 26 patients had been known to have renal disease for from two to nineteen years, the majority for from two to nine years. The value returned to normal in 4 of these cases while treatment was being given in the hospital following the primary admission. In 8 more cases the values obtained on primary admission were decreased but were still above normal limits at the time of dismissal. The concentration of blood urea in 3 of the 8 cases later returned to normal. Also in 3 of the 26 cases the value for blood urea was elevated on primary admission, rose still higher while treatment was being given and was still elevated on dismissal; the value had returned to normal, however, at a later reexamination. This makes a total of 10 of these 26 patients whose measurable renal insufficiency evidently improved sufficiently to reach normal either while under treatment at the clinic or after their dismissal.

Four of the 72 patients had had the disease eleven years or longer. The values for blood urea were normal when they were first examined. The concentration of the blood urea of a fifth patient on primary admission, who also had had the disease eleven years or longer, was elevated to 46 mg. per hundred cubic centimeters.

Nine of the 72 patients had blood urea of normal concentration at the time of the first admission but gave evidence of renal insufficiency on reexamination. All 9 patients had had the disease from two to eight years when this elevation in value for blood urea was noted. In 4 of these 9 cases hypertension was an associated condition and, in all, apparently the hypertension was progressive.

We took 4,250,000 to 5,250,000 per cubic millimeter of blood as the normal erythrocyte count. For females 13 to 16 Gm. per hundred cubic centimeters of blood, and for males 14 to 17 Gm. was taken as the normal concentration of hemoglobin. By the foregoing standards 43 of the 72 patients were anemic on primary admission. Anemia finally develops in most cases of chronic nephritis. The lowest erythrocyte count was 2,040,000 and the lowest hemoglobin determination was 6.8 Gm. per hundred cubic centimeters. The leukocyte counts of 23 patients were increased when they were

first admitted; the highest leukocyte count was 16,200 per cubic millimeter of blood. By the foregoing standards, of the 38 patients later reexamined 8 who previously had been anemic gave normal values at reexamination; however, on reexamination 6 patients were anemic who had not been anemic on primary admission. The treatment of anemia in the presence of chronic nephritis is difficult.

Of 29 patients whose basal metabolic rates were estimated, 9 gave readings of more than —10 per cent on primary admission. In no case was the rate more than +10 per cent. The basal metabolic rates of 2 patients were —25 and —37 per cent. Also the blood cholesterol values of both of these patients were elevated respectively to 893 and 1,190 mg. per hundred cubic centimeters. The laboratory picture, therefore, resembled that seen in myxedema. Desiccated thyroid was used as an adjunct in treatment of these 2 patients. Both were working part time when this report was written.

Using determinations of blood pressure of 150 mm. of mercury systolic and 90 mm. of mercury diastolic as arbitrarily taken upper limits of normal, 27 of 38 patients who were reexamined had normal blood pressures at the time of the reexamination. Seven of these 27 patients had had hypertension at a previous visit. At the time of reexamination, hypertension was present in the 11 remaining cases of the 38. In 6 of these 11 cases the hypertension apparently had developed since the previous visit, while in the other 5 cases it had been present at a previous visit and had continued. The patients with hypertension represented all decades of life from the teens to the seventies. They had had renal disease for from two to nine years when hypertension developed; this period of antecedent renal disease is like that encountered in the cases of renal insufficiency. Four of the 11 patients with hypertension complained of exertional dyspnea and 4 of headache. These two groups of 4 overlap. This type of headache usually is frontal, is present in the early morning, on awakening, and usually lasts one to two hours.

Two of the 72 patients, both men, aged 18 and 24 years respectively, presented the ophthalmoscopic picture of developing retinitis.⁸ One had had knowledge of his renal disease for eight years and the other for two years. Also in both cases hypertension and nitrogen retention had developed since the patients first had been examined at the clinic. They both continued to have some clinical edema.

Retinitis at times may be reversible. In the ocular fundi of 4 patients were signs indicating regression of previous retinitis. Two of these patients, whose blood pressures had been elevated when they first had been seen at the clinic, had normal blood pressures at the time of their last visits. Slight nitrogen retention was found in examination of 3 of these 4 patients when they were last examined.

Using the microscopic evidence of erythrocyturia, leukocyturia and cylindruria, and the presence of albuminuria as criteria, 20 of the 38 patients reexamined gave evidence of improvement in urinary findings on reexamination; 11 of these patients showed some improvement, 5 showed definite improvement and the

urine of 4 was normal. These studies of the urinary sediment indicate that at the time of these examinations the disease was relatively quiescent but, as Addis and Oliver⁹ and Christian¹⁰ have pointed out, qualitative observations of the urinary sediment are only now and then decisive and are not prognostic.

In all cases in which values for plasma fibrinogen were determined, the results were within the normal limits of 300 to 600 mg. per hundred cubic centimeters. A tendency to bleeding was not exhibited by any patient following the use of acacia.

This follow-up study indicates that many of the patients who had resistant nephrotic edema and who were treated successfully with acacia and other treatments discussed have been able to maintain a more nearly normal economic and social existence than they had been able to lead before treatment. As was said in an earlier paragraph, we could not find any evidence that acacia was harmful in any way to these patients.

SEPTICEMIA AND BACTERIAL ENDOCARDITIS RESULTING FROM HEROIN ADDICTION

REPORT OF FIVE CASES

HUGH HUDSON HUSSEY, M.D.

BERTRAM F. SCHAEFER, M.D.

AND

BERNARD J. WALSH, M.D.

WASHINGTON, D. C.

The development of bacterial infection of the blood stream in narcotic addicts as a result of their addiction is a rare occurrence. This is somewhat surprising in view of the fact that so many addicts use morphine or heroin by injection and entirely without antiseptic technic. Most¹ has reported on the epidemiologic and clinical aspects of more than 200 cases of malaria in drug addicts in New York City. Apparently this disease is not uncommon, being spread through groups of addicts as a result of contamination of their injection equipment with blood containing the parasites. This assumption is based on the fact that it is common practice for addicts to employ a single syringe and needle for a series of injections in different individuals without the slightest attention to cleansing of the equipment between injections. Doane² reviewed the literature on the subject of tetanus acquired by narcotic addicts presumably as the result of using contaminated equipment for injection. He added 3 cases to the total of 9 cases previously reported by other authors. In addition, there have been several reports³ on the occurrence of

blood stream infection by *Monilia* in drug addicts, and in 3 cases mycotic endocarditis was found.

Over a period of about a year we have observed 5 cases of septicemia in heroin addicts, 4 of whom had acute bacterial endocarditis. Because the development of septicemia under these circumstances is unusual, these cases are reported here in detail.

REPORT OF CASES

CASE 1.—A man aged 45, Chinese, was admitted to the Psychiatric Division of the Gallinger Municipal Hospital for the treatment of heroin addiction of several years' standing. Because of language difficulties it was impossible to obtain an adequate history. He appeared acutely ill and had labored respirations. The blood pressure was 140/70, temperature 101 F., pulse rate 100 and respiratory rate 36. There were many needle puncture marks along the veins of both upper extremities. Several infected ulcers were present over the middle third of the left tibia. Three petechiae were visible in the left palpebral conjunctiva. Over the lower half of the right lung there were found diminished tactile fremitus and impaired resonance. Bronchovesicular breathing and subcrepitant rales were heard in this same area. A soft, nonradiating, apical systolic murmur could be heard. His abdomen was distended and tympanitic. Urinalysis showed 2 plus albumin, 2 granular casts and 18 red cells per high power field. The red blood cell count was 2,630,000, the white blood cell count 25,000 with 80 per cent polymorphonuclears, 13 per cent young forms, and 7 per cent lymphocytes. Type XXIV pneumococcus was found in the sputum. A blood culture taken on admission was negative.

Sulfathiazole was started on admission, and adequate levels were obtained. An x-ray film of the chest on the second hospital day showed diffuse pneumonitis in the lower half of the right lung. There was no apparent change during the ensuing two weeks except for the appearance of several petechiae on the hands and feet. His temperature fluctuated between 99 and 104 F. Severe chills occurred almost daily, but blood cultures were repeatedly negative. The white blood cell count remained elevated.

On the fifteenth hospital day sulfathiazole was discontinued and sulfadiazine started. An x-ray film of the chest showed some clearing of the pneumonitis at the right base. The chills continued, however, and on the sixteenth, seventeenth and eighteenth days positive blood cultures were obtained by another laboratory and *Bacillus pyocyaneus* was grown. New petechiae appeared on the chest and extremities, and the patient looked more severely ill and irrational. There was no change in the character of the temperature curve. On the nineteenth hospital day a short, high pitched early diastolic murmur of low intensity was heard in the second left intercostal space next to the sternum.

The remainder of the clinical course was steadily downhill. There were no significant alterations in the physical and laboratory findings. In view of the reported beneficial effects from the use of acetic acid in the treatment of *B. pyocyaneus* infection of the skin, and because the sulfonamides had shown no ameliorating influence on the disease in this case, 100 cc. of 1 per cent acetic acid solution was given by vein daily for five days. There was no observable effect from this treatment. The patient died on the thirty-ninth hospital day.

At necropsy the heart weighed 620 Gm. and was moderately dilated. The pericardial cavity was completely obliterated as the result of fibrinous pericarditis. The heart valves were the normal except for a large, soft friable vegetation on the anterior cusp of the aortic valve. Just above this leaflet there was a mycotic aneurysm 3 cm. wide and 2 cm. deep. A culture of the vegetation was positive for *B. pyocyaneus*. The spleen weighed 350 Gm., was quite firm and contained 3 infarcts. There were also numerous small infarcts in the kidneys.

CASE 2.—C. S., a Negro aged 38, was admitted to the hospital because of cough and loss of weight. His illness had begun three months before admission with cough, anorexia and night sweats. On the advice of a friend the patient began taking heroin intravenously as a tonic. The drug had been administered daily by vein without use of antiseptic precautions of any kind. During the three months he had lost 18 pounds (8 Kg.) in weight. Just prior to admission he had become weak, dyspneic and febrile. A roentgenogram of the chest taken one week before admission had been reported as negative.

On examination the patient looked acutely ill and dyspneic. The temperature was 102.5 F., pulse 125, respiratory rate 32, blood pressure 110/68. The forearms showed scars along the veins at the sites of injection of heroin. The breath sounds were diminished and there were subcrepitant rales over the posterior aspect of the left lung at the base. The remainder of the physical examination was negative.

The urinalysis was normal. There were slight leukocytosis and mild anemia. An x-ray film of the chest showed areas of increased density in the lower half of the left lung and a slight increase in the transverse diameter of the heart. A blood culture taken on the third hospital day was reported to show *Staphylococcus albus*, but several subsequent cultures yielded *Staphylococcus aureus* which was coagulase positive. An x-ray film of the chest made on the seventh day revealed discrete areas of soft infiltration containing radiolucent centers scattered throughout both lungs.

The patient was given sulfamerazine, and adequate blood levels were maintained. His course was septic and rapidly downward. On several occasions he coughed up blood tinged sputum. Except for the development of rales in additional areas of the lungs, there were no new physical findings. The white blood cell count ranged between 18,000 and 21,000. He died on the fourteenth hospital day.

At necropsy the heart weighed 325 Gm. The valves were normal except the tricuspid, which was the site of a large mass of soft vegetations. Both lungs contained innumerable small abscesses of embolic origin. Cultures from the vegetations and from the lung abscesses yielded *Staphylococcus aureus*. The spleen was moderately enlarged.

CASE 3.—O. B., a Negro woman aged 25, was acutely ill when admitted to the hospital, and her history was vague. She was about six months pregnant and had been well until a few weeks before admission. Then she had developed fever, vomiting and symptoms of a respiratory infection, including sore throat and cough. Six days prior to admission she had anointed her skin first with alcohol and then with camphorated oil for relief of headache. The next day blebs had appeared on her skin, and the following day peeling had begun.

The patient looked stuporous and seriously ill. The temperature was 102.5 F., pulse 130, respiratory rate 48, blood pressure 120/70. The face was swollen, and there was extensive patchy exfoliation of the skin of the arms and chest with many cracked and bleeding areas. On the arms were several flattened bullous lesions. The mucous membranes and tongue were dry, and the pharynx was congested. At the base of the right lung resonance was diminished, and there were subcrepitant rales in both axillae and at the right base. The heart was normal in size. There was a short soft systolic murmur on the left of the sternum and a gallop rhythm. The uterus was enlarged to the level of the umbilicus. The fetal heart sounds were distinctly audible. Extensive raw areas were seen around the vulva.

Urinalysis showed albumin (1 plus), there was moderately severe anemia and the leukocyte count was 20,500. A blood culture taken on the first day yielded *Staphylococcus aureus*, and this organism was repeatedly obtained. The blood urea nitrogen was 16 mg. per hundred cubic centimeters. An x-ray film of the chest showed soft areas of infiltration scattered throughout both lung fields suggesting pulmonary infarcts.

The patient lived nine days after entering the hospital. She was treated with sulfamerazine for two days and then with

penicillin until the time of her death. The hematologic and bacteriologic findings remained the same, but the patient's general appearance improved temporarily after penicillin was started. High fever and tachycardia continued, however, and after the sixth day she became rapidly weaker. The fetal heart sounds were last heard on this day.

After she died it was learned from the patient's husband that she had been addicted to the use of heroin administered intravenously without aseptic precautions.

At necropsy the heart weighed 320 Gm. There were 3 gray, warty vegetations on the tricuspid valve. The other valves were not affected, and none of the valves showed evidence of preexisting disease. The peripheral parts of the lungs were filled with numerous small septic infarcts, many of which had formed abscesses. The liver was greatly enlarged as the result of cloudy swelling, and the spleen was slightly enlarged.

CASE 4.—A Negro aged 33, the husband of patient 3, was admitted to the hospital because of an abscess of the left antecubital fossa and for diabetic control. The patient had administered heroin to himself at irregular intervals by the intravenous route for seven years. However, for the preceding three months he had used the drug three times daily. Sterile precautions were not observed at any time, and on several occasions abscesses had developed at the sites of injection. The infection of the left antecubital space had been present for about a week. He stated that he and his wife used the same syringe and needle.

The only significant findings on examination included many scars along the veins of both upper extremities and an area in the left antecubital fossa which was swollen, warm, red, tender and firm. The temperature was 102 F., pulse 110, respiratory rate 20 and blood pressure 130/80.

Urinalysis showed 4 plus reduction of Benedict's solution. The red blood cell count was 4,270,000, the white blood cell count 11,300. The blood sugar was 400 mg. per hundred cubic centimeters. A blood culture taken on admission was negative. An x-ray film of the left elbow showed no evidence of bone or joint disease.

After two days of application of hot saline soaks to the area of cellulitis the patient's temperature returned to normal and the inflammation appeared to be subsiding. On the seventh and ninth days his temperature rose to 100 F. and on the eleventh day he had a severe chill with a rise in temperature to 103 F. His temperature remained elevated and fluctuated between 99 and 103 F. for the ensuing five days, during which time three positive blood cultures for *Staphylococcus aureus* were obtained. At this time the patient looked acutely ill and complained of profound weakness and severe generalized aches and headache. Sulfamerazine was started and adequate levels maintained. The temperature gradually fell to normal during the next six days and the patient appeared much improved. Three positive blood cultures for *Staphylococcus albus* were reported for this period. The local infection in the antecubital fossa became fluctuant and was incised. A small amount of pus containing *Staphylococcus aureus* was evacuated. Sulfamerazine was discontinued at this time and penicillin administered by the intramuscular route for the next seven days. No further positive blood cultures were obtained. The patient continued to improve, and the incision healed completely. Diabetic control was unsatisfactory during the first three weeks of hospitalization but was well established from then until his discharge on the fifty-fourth hospital day.

CASE 5.—F. N., a Negro woman aged 28, entered the hospital complaining of pain in the upper half of the left hemithorax. Ten days before admission she had experienced chilliness followed by a feeling of fever. These symptoms had recurred repeatedly each day afterward. After four days she had suddenly been stricken with sharp pain in the left pectoral region. Cough had then begun and had noticeably aggravated the pain. Her private physician had informed her that she had pleurisy, and sulfathiazole had been prescribed. The cough later had become productive of thick brown sputum.

The patient had been taking heroin intravenously for four months, during which time there had been a loss in weight of 50 pounds (23 Kg.). The syringe and needle used for injections had not been sterilized at any time.

On examination the patient looked acutely ill and emaciated. The temperature was 102.8 F., pulse rate 110, respiratory rate 32 and blood pressure 100/75. Both forearms were scarred along the course of the veins. There were bronchovesicular breath sounds and subcrepitant rales over the left upper lobe. The heart was normal except for a soft apical systolic murmur.

Urinalysis showed a trace of albumin. There was moderately severe anemia, and the leukocyte count was 6,400 with 75 per cent neutrophils and 25 per cent lymphocytes. Smears for malaria were negative. X-ray examination of the chest showed small areas of infiltration in the left upper lobe. Blood cultures were repeatedly positive for *Staphylococcus aureus*.

The patient lived thirty-one days after entering the hospital. Her clinical course was septic and steadily downward. She was treated with sulfamerazine without any effect on either the course or the positive blood cultures. Subsequent x-ray films of the chest demonstrated clearing of the infiltration in the left upper lobe and the appearance of numerous new areas of involvement which were interpreted as pulmonary infarcts. From time to time there was expectoration of fresh blood, but the physical findings in general were not altered except for variation in the location of pulmonary rales.

At postmortem examination the heart was not enlarged. There was acute bacterial endocarditis of the tricuspid valve, the picture in general being similar to that of the other cases. There were many small pulmonary infarcts, all of which had undergone abscess formation. There was empyema of the right pleural cavity. The spleen was moderately enlarged.

COMMENT

As far as we have been able to determine from the literature and from Dr. Edwin G. Williams of the United States Public Health Service, septicemia due to ordinary organisms must be very uncommon in narcotic addicts. In 4 of the 5 cases reported here the causative organism was *Staphylococcus aureus* and in one *Bacillus pyocyaneus*.

None of the patients used any antiseptic precaution in the self administration of the heroin. There are, therefore, several possible modes by which blood stream infection may have occurred. First, the material used may have contained pathogenic bacteria. In general, heroin used by addicts is mixed with various agents for the purpose of adding bulk. One such common adulterant is lactose, which perhaps would improve the mixture as a culture medium. Second, the equipment used in the administration of the heroin was not sterilized and was often passed from one addict to another without cleansing. Third, failure to apply an antiseptic to the skin before injection of heroin intravenously may have permitted the introduction into the blood stream of organisms inhabiting the skin. Fourth, in case 4 the source of the septicemia may have been the abscess which had developed at a site of injection. Presumably, of course, the abscess had its inception by one of the mechanisms previously mentioned. There is no way to determine definitely which of these possible modes of infection operated in these cases. However, the fact that cases 3, 4 and 5 were closely associated chronologically suggests that the heroin was contaminated. On the other hand, patients 3 and 4 were husband and wife, who used a syringe in common.

It is not particularly surprising that acute bacterial endocarditis developed in 4 of these 5 cases of septicemia. However, localization of the lesion on the tri-

cuspid valve alone in 3 of the cases is noteworthy because of its rarity. For example, in a series of 646 cases of acute bacterial endocarditis reported by Goldburgh, Baer and Lieber⁴ the tricuspid valve alone was involved in only 20 cases (3.1 per cent). In the remaining case the aortic valve alone was affected. There was no evidence of preexisting valvular disease in any of the cases.

The diagnosis of acute endocarditis was readily apparent in case 1. Manifestations of septicemia, repeatedly positive blood cultures, petechiae and the appearance of an aortic diastolic murmur indicated the existence of bacterial endocarditis of the aortic valve.

In cases of endocarditis involving the right side of the heart the diagnosis may be less apparent. In the 3 cases of this group the presence of septicemia was obvious from the clinical course and the positive blood cultures for *Staphylococcus aureus*. However, the onset of manifestations of pulmonary infarction indicated the need for discovering a source of the emboli. The absence of any such source in the peripheral veins permitted the deduction that there was right sided endocarditis. The failure to detect a murmur in any case was strong ground for concluding that the tricuspid valve was the seat of the endocarditis. There was no evidence of embolic phenomena in the systemic circulation in any of these cases, and it is interesting that in spite of the presence of staphylococcic septicemia abscesses were found only in the lungs. The diagnostic features of these 3 cases have been discussed in greater detail elsewhere.⁶

The treatment in the 4 cases of endocarditis included the use of average doses of one of the sulfonamides in each case and of penicillin in 1 case. The outcome was uniformly fatal. In case 4, in which there was a large staphylococcic abscess of the antecubital fossa and *Staphylococcus aureus* septicemia but no endocarditis, incision and drainage of the abscess, sulfamerazine and penicillin successfully controlled the infection.

SUMMARY

In 4 of 5 cases of septicemia in heroin addicts death followed the development of acute bacterial endocarditis, which in 3 instances involved the tricuspid valve alone. Three of the cases of endocarditis were due to *Staphylococcus aureus* and the fourth to *Bacillus pyocyaneus*. In the 1 case of *Staphylococcus aureus* septicemia without endocarditis, recovery occurred.

Mental Exhaustion from Intellectual Effort.—Bearing on this subject, I, like others of our profession, have had repeated occasion to observe the effect of overwork on gentlemen who use their brains with an expenditure of energy inconceivable to the thoughtless—men of widespread mercantile affairs, men engaged in money transactions on a large and anxious scale. The condition of such patients attested the applicability of these remarks by their mental and physical exhaustion, by their depression of spirits and by their want of self confidence. Yet, with such men, the restoration to health has been made complete by mental leisure, by "going out of town" and taking plenty of exercise in the open air, while abstaining from the real disturbing cause, their business.—Hilton, John: *Rest and Pain*, London, George Bell & Sons, 1857.

THE TREATMENT OF EARLY AND LATENT SYPHILIS

IN NINE TO TWELVE WEEKS WITH TRIWEEKLY INJECTIONS OF MAPHARSEN

A PRELIMINARY ANALYSIS OF THE RESULTS IN THE FIRST 4,823 CASES

HARRY EAGLE, M.D.

BALTIMORE

The pioneer work of Chargin, Leifer, Hyman and their associates¹ with the five day intravenous drip has stimulated a large number of clinical studies on other intensive methods of antisyphilitic treatment.² The duration of treatment has been varied from one day to twenty weeks, the frequency of injections has been varied from twice daily to twice weekly, and in some clinics artificially induced fever has been used as an adjunct to the intensified course of arsenotherapy.

As with any chemotherapeutic procedure, the three major considerations which determine the utility of these treatment schemes are their therapeutic efficacy, their toxicity and their practicability. Recent studies in experimental rabbit syphilis provide a helpful orientation to the first two of these points. The total curative dose of mapharsen was found to be more or less constant, largely independent either of the frequency of injections or of the duration of treatment.³ On the other hand, the toxicity of the drug varied directly with the method of administration. The shorter the time period over which the mapharsen was administered and the fewer the injections, the greater was its toxicity⁴ and the smaller was the margin of safety provided by a given therapeutic dose.⁵

In man also the curative dose of mapharsen has been found to be essentially the same, regardless of the method of administration.⁶ From the animal data it was therefore to have been anticipated that, the shorter the time period into which the curative dose of mapharsen was compressed, the greater would be the incidence of serious toxic reactions and death. That has been fully borne out in practice. Thus, weekly injections of 60 mg. of mapharsen represent approximately one tenth the maximal tolerated dose in animals; and, corresponding to that wide margin of safety, the mortality in man following routine weekly treatment at this dosage level has been on the order of 1:5,000 or less.⁶ On the other hand, when the total therapeutic dose of 1,200 mg. of mapharsen was compressed into five days, the calculated margin of safety⁵ was only 2.0, and the observed mortality with this schedule in man has been on the order of 1:200. Between these two extremes, schedules of intermediate degrees of toxicity, providing intermediate margins of safety.

Owing to limitations of space, tables 1 and 6 appear in reprints only. From the U. S. Public Health Service Venereal Disease Research and Postgraduate Training Center, Johns Hopkins Hospital.
Read in a panel discussion on "Intensive Therapy of Early Syphilis, with Special Reference to Arsenotherapy Either Alone or Combined with Other Agents," before the Section on Dermatology and Syphilology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

necessarily result in a correspondingly intermediate morbidity and mortality (chart 1).

On the basis of the animal data there was reason to believe that a treatment schedule involving injections of mapharsen repeated three times weekly at a unit dose of approximately 1 mg. per kilogram represented a reasonable compromise between speed and safety. This schedule in animals provided a safety factor of 6 to 8.⁵ Corresponding to that large margin of safety, it was anticipated that the mortality in man would be less than 1:1,000 and that such a schedule would permit the definitive treatment of early and perhaps of latent syphilis in outpatient clinics within a period of six to twelve weeks. The clinical study was begun in October 1941 with the cooperation of hospital, state, county and municipal venereal disease clinics. The number of participating clinics gradually increased, reaching 86 as of March 1, 1944. These clinics are listed in table 1.

With the exception of those cases treated in Marine hospitals and a few other hospital clinics, all patients were treated as ambulatory outpatients. The dosage was adjusted to body weight, at first with ten different

Chart 1.—Mortality of various treatment schedules in man as a function of the margin of safety, calculated from experimental data.

dosage scales, but later with five, as indicated in table 2. The average dose was 60 mg.; the maximum was arbitrarily set at 80 and the minimum at 40 mg. No distinction was made between the sexes. The duration of treatment was varied from four to twelve weeks in order to ascertain the minimum total amount of treatment which would give satisfactory results. In approximately half the clinics the patients were given weekly injections of a bismuth compound concomitant with the arsenical in order to determine the degree to which the end results would be affected by the administration of heavy metal. Although the choice of the bismuth preparation was left to the discretion of the clinic director, 80 per cent of those receiving bismuth were given the bismuth subsalicylate at an average dose of 0.2 Gm., equivalent to 0.13 Gm. of bismuth metal. The clinics were urged to do quantitative rather than qualitative serologic tests in order to permit the detection of serologic relapse in patients not yet seronegative; and it was asked that such tests be repeated at least twice during the period of treatment, and monthly thereafter. It was further requested that a spinal puncture be done three months after the completion of treatment and repeated at the end of a year if feasible.

The present preliminary report is based on the early results in the first 4,823 patients on whom treatment records were submitted for analysis. Although the proportion of patients observed for a year or longer has been small (cf. table 3), it is nevertheless believed that the method of analysis permits preliminary conclusions

with latent syphilis. There were 151 patients previously treated for early syphilis and now diagnosed as presenting infectious relapse or serologic relapse, and 8 with late recurrent syphilis. Forty per cent of the total were white and 53 per cent were male. The amounts of treatment received, expressed both as the number of injections and as the total milligrams per kilogram of body weight, are listed in table 4.

patient and occurred in varying combination. In order of decreasing frequency they consisted of fever, rash, vomiting, headache, conjunctivitis and photophobia, and facial edema. Most of these patients recovered completely in forty-eight to seventy-two hours. In 24 of 62 patients tested in that respect soon after recovery.

This tendency for serious reactions to occur in women is of particular interest in relation to the treatment of syphilis in the armed forces. In the 2,583 men represented in the present study no deaths occurred, there were 14 serious reactions, including 11 cases of jaundice, and treatment had to be discontinued for any reason in a total of only 48.

THERAPEUTIC RESULTS IN EARLY SYPHILIS

When the mapharsen was given alone, without bismuth, the results were uniformly poor, regardless of the amount of arsenical administered. The number of observed failures per hundred patients treated differed but little in patients receiving a total of less than 15, 15 to 20, 21 to 26 or 27 or more mg. of mapharsen per kilogram (15, 9, 15 and 10 per cent treatment failures respectively, cf. table 7). However, when bismuth was given along with the mapharsen the results were consistently better, and the optimum results far exceeded those it was possible to attain with mapharsen alone. In patients receiving a total of 15 to 20, 21 to 26 and 27 or more mg. of mapharsen per kilogram plus an average of six, eight and ten injections of bismuth respectively, the incidence of observed treatment failures was 6.6, 1.5 and 1.1 per cent respectively.

These figures are of relative rather than absolute significance because of the large proportion of patients who disappeared from observation. A statistically more reliable comparison is afforded by the cumulative percentage of treatment failure and the cumulative percentage of "cure" calculated by the method illustrated in table 5. The results are in complete agreement with those obtained by the crude method of analysis that has been outlined. As shown in charts 2 and 3, mapharsen alone (the open circles and triangles in charts 2 and 3) gave uniformly poor results.

The addition of an average of only five injections of bismuth to the smaller amount of mapharsen (less than

Chart 2.—Cumulative percentage of treatment failure in patients treated triweekly, in relation to the total dose of mapharsen and bismuth.

actual sensitization to mapharsen was demonstrated in that small doses precipitated the same syndrome; and in a total of 54 patients, or 1 in every 90 patients treated, it was necessary to discontinue arsenical treatment. It is of interest that 70 per cent of these reactions occurred in the second to fourth week of treatment and 60 per cent in the second week, between the eighth and the fourteenth day of treatment. The time period, coupled with the high frequency of an associated toxic rash, suggests a close relationship of this syndrome to so-called erythema of the ninth day.

Serious toxic reactions occurred in a total of 39 patients. They consisted of 2 cases of toxic encephalopathy (1:2,400), 7 cases of arsenical dermatitis (1:700), 4 of nephritis (1:1,200), 5 of blood dyscrasia (1:950) and, as the most frequent complication, 21 cases of jaundice (1:250). As with the "sensitization syndrome," 40 per cent of these serious reactions occurred in the second week of treatment and 75 per cent in the second to the fourth week. In general, toxic reactions occurred most frequently during the second week of treatment; beyond that period there was progressively decreasing likelihood of a serious toxic complication.

There were four deaths in the entire series of 4,823 patients: 2 cases of nephritis, 1 of toxic encephalopathy and 1 of jaundice, all occurring in the second to fourth week of treatment. This mortality of 1:1,200 is reasonably close to that anticipated on the basis of animal data but should be further qualified in that two, and perhaps three, of these deaths may have been preventable. With reasonably good medical care the mortality on the triweekly schedule may therefore be 1:2,000 or less rather than 1:1,200.

Unlike the mild reactions to mapharsen, and unlike the syndrome suggestive of sensitization to mapharsen, serious toxic reactions tended to occur in women, in young patients and in Negroes. Thus, all four deaths were in Negro women, 3 of whom were under 18.

Chart 3.—Cumulative percentage of "cure" in patients treated triweekly, in relation to the total dose of mapharsen and bismuth.

21 mg. per kilogram) significantly decreased the percentage of definite failure and increased the percentage of "cure" in fifty to sixty weeks from 49 to 65. When an average of nine injections of bismuth was added to the larger amount of mapharsen (21 mg. per kilogram or more) the cumulative percentage of treatment failure seventy weeks after beginning treatment fell to 9.3, and

82 per cent of the patients were seronegative and "cured," with the remainder of the cases still pending (closed circles in charts 2 and 3).

In summary, at least in the triweekly schedule, and perhaps in other intensified forms of arsenotherapy as

well, mapharsen should be supplemented by bismuth for optimum results. In the absence of heavy metal a relatively small amount of mapharsen (up to 20 mg. per kilogram, averaging a total of 800 mg.) "cured" half of the patients, and even twice that amount, an

Comment: No demonstrable correlation between the incidence of observed treatment failure and either race, sex, initial serologic titer or the duration of treatment. As in the entire series, fewer failures were observed in seropositive primary syphilis than in secondary syphilis. There was certainly no evidence that the latter has a more favorable prognosis because of a putative immunity.

1. Titer = highest dilution of serum giving a definitely positive result.

average total of approximately 1,600 mg., "cured" less than two thirds. However, with simultaneous weekly injections of bismuth (0.2 Gm. of bismuth subsalicylate), triweekly injections of mapharsen at individual doses of approximately 1 mg. per kilogram (40 to 80 mg. per injection) continued for nine to twelve weeks will apparently "cure" at least 80 per cent, and probably closer to 90 per cent, of cases of early syphilis.

Relative Importance of Mapharsen and Bismuth.—Given the fact that the simultaneous administration of bismuth so materially affected the results attained by the triweekly administration of mapharsen, the question arises as to the relative importance of the arsenical and of the bismuth. The data of table 7 provide a partial answer to that question. When both mapharsen and bismuth were used, an increase in the amount of either drug led to more favorable results. A relatively small amount of mapharsen (15 to 20 mg. per kilogram) supplemented by nine injections or more of bismuth gave results comparable to those achieved by larger amounts of mapharsen with smaller amounts of bismuth. In that sense the drugs were mutually supplementary. However, even the largest amount of mapharsen alone (27 or more mg. per kilogram, averaging 30) was less effective than relatively small amounts of mapharsen and bismuth used in conjunction (15 to 20 mg. of

mapharsen per kilogram plus approximately six injections of bismuth). The two drugs are apparently not merely additive but actually synergistic in their therapeutic effects. This suggests that they may exert their spirocheticidal action by affecting different vital functions of the organism.

The question may be raised as to whether the striking adjuvant role of bismuth may not be more apparent than real. It is conceivable that the deposit of insoluble bismuth subsalicylate serves merely to postpone infectious or serologic relapse. Although this is unlikely, and although the rate at which patients failed gave no indication that such was the case, several years' observation will be necessary before this possibility can be dismissed from consideration.

MISCELLANEOUS CONSIDERATIONS

Type of Failure.—As indicated in table 6, infections relapse and serologic relapse accounted for 43 and 40 per cent of the observed treatment failures. A large proportion of the serologic relapses were diagnosed in patients who had never been seronegative, by virtue of a sustained and continuing rise in the serum reagin content, quantitatively titered. Central nervous system involvement accounted for an additional 13 per cent, half of these being asymptomatic; and 7 per cent of the

failures were of patients whose serologic findings were positive at a stationary level one year after the beginning of treatment. The degree to which the central nervous system failures represented cases of central nervous system involvement at the time treatment was begun is an open question.

Outcome as Influenced by Stage of Infection.—On the basis of previous studies, the prognosis of early syphilis is generally considered better in secondary syphilis than in the seropositive primary stage.⁷ In explanation it is usually assumed that the patient with secondary syphilis has had time to develop a certain degree of immunity. However, the present study gave no indication of a more favorable prognosis in secondary syphilis.

Relapsing and Recurrent Syphilis.—In patients with previously treated early syphilis who had relapsed, the number of treatment failures significantly exceeded those obtained in previously untreated syphilis, but only when mapharsen was given alone, without bismuth. In those patients who received mapharsen plus bismuth, the prognosis was apparently no less favorable than in previously untreated cases. However, the number of

7. Moore, J. E.: The Modern Treatment of Syphilis, ed. 2, Springfield, Ill., Charles C Thomas, Publisher, 1941. pp. 581-588

patients was small, and further experience and observation may alter the picture unfavorably (table 10).

Rate of Serologic Reversal.—Although, as shown in table 9, the initial serologic titer had no effect on the prognosis of early syphilis, it did materially affect the time required for serologic reversal. As is shown in chart 4, in a group of patients who received similar amounts of treatment (21 to 26 mg. of mapharsen, plus bismuth), those with a low reagin titer attained seronegativity considerably faster, on the average, than those with initially high titers. It is of interest that the rate at which the serum reagin titer fell, and the rate at which patients became seronegative, were the same in this semi-intensive schedule of treatment as in the traditional method of weekly injections.

The question comes up as to the relative efficacy of treatment when the same total dosage of mapharsen was spread over a longer time period, either because treatment was irregular or because the individual dose was smaller than that indicated in table 2. On the basis of the animal data³ one would have anticipated little or no difference in the end results; and that has been the experience in the present study. As shown in the last section of table 9, in patients receiving similar total amounts of treatment (21 to 26 mg. of mapharsen per kilogram), all of whom also received bismuth, there was no significant difference in the number of observed failures if treatment was completed in less than fifty-eight days (averaging fifty-four), in fifty-eight to seventy-seven days (averaging sixty-six) or in more than seventy-seven days (averaging eighty-one). Within these limits, occasional lapses in treatment or the use of e. g. a biweekly instead of a triweekly schedule had no effect on therapeutic efficacy. The important consideration was the total amount of drug received rather than the intensity or regularity of its administration.

Latent Syphilis.—In 945 of the 1,190 cases of latent syphilis included in the present study, no previous treatment had been given and they were diagnosed on serologic grounds alone. In 279 of these the disease was believed to be of less than two years' duration. In this presumably most favorable group, 99 were given the schedule of treatment found to be most effective in early syphilis (more than 21 or more mg. of mapharsen

rather permanent freedom from symptoms, and since a relatively small amount of standard weekly treatment apparently suffices for that purpose,⁸ there is every reason to anticipate that an intensive schedule of treatment which is adequate for early syphilis will be equally satisfactory for the treatment of latent syphilis. Because

316 cases of secondary syphilis, similarly treated
(21-26 mg./kg. mapharsen + bismuth)

Chart 4.—Rate at which patients became seronegative, in relation to the initial serum reagin titer.

of the generally favorable prognosis of latent syphilis, even with little or no treatment, many years' observation of a large group of patients will be necessary to establish this point.

SUMMARY

1. A total of 4,823 patients, including 3,394 cases of primary and secondary, 1,190 of latent and 159 of recurrent or relapsing syphilis, have been treated with triweekly injections of mapharsen at approximately 1 mg. per kilogram per injection, with a maximum of 80 mg. and a minimum of 40. Two thirds of the patients were given concomitant weekly injections of a bismuth compound, usually bismuth subsalicylate (0.2 Gm.).

2. Treatment had to be interrupted because of toxic reactions in a total of 106 patients. Thirty-nine of these were serious reactions, with jaundice the most common complication. Four patients died. It is believed that at least two of these deaths were preventable and that the mortality of the triweekly schedule is on the order of 1:2,000. The incidence of toxic reactions was highest in young Negro women, and there were no deaths in the 2,583 men.

3. Triweekly injections of mapharsen alone, without bismuth, gave uniformly poor therapeutic results, regardless of dosage.

4. Triweekly injections of mapharsen in conjunction with weekly injections of bismuth proved highly effective. In patients receiving an average total of 1,600 mg. (21 mg. per kilogram or more) plus an average total of nine injections of bismuth, the cumulative percentage of treatment failure was 9.3 and the cumulative percentage of "cure" fifty to sixty weeks after the beginning of treatment was 82 per cent. A decrease in either mapharsen or bismuth to less than these amounts resulted in a higher proportion of treatment failure.

TABLE 10.—The Relative Incidence of Treatment Failure in Relapsing or Recurrent Syphilis, Compared with Previously Untreated Early Syphilis

	Primary and Secondary Syphilis		Infectious Relapse, Serologic Relapse and Recurrent Syphilis	
	Without Bismuth	With Bismuth	Without Bismuth	With Bismuth
Number of patients.....	1,135	2,241	59	70
Average period of observation.....	28	21	33	26
Number of failures.....	152	56	21	2
Incidence of apparent failure, %...	13.4	2.5	35.6	2.8

Comment: In patients who received only mapharsen, the relapsing group gave significantly more failures: In patients who received bismuth as well as mapharsen there was no significant difference in the prognosis of recurrent or relapsing syphilis and previously untreated cases of early syphilis.

per kilogram, with simultaneous weekly injections of bismuth). Of these only 25 had become seronegative during a varying period of observation. This is consistent with the results obtained with routine standard methods of treatment.⁸ However, since the goal of treatment in latent syphilis is not seronegativity but

8. Discker, T. H.; Clark, E. G., and Moore, J. E.: Long-Term Results in the Treatment of Latent Syphilis. *Am. J. Syph., Genor. & Ven. Dis.* 28: 1:26, 1944.

5. Although these results are tentative, based on the prolonged observation of as yet a small proportion of the total patients treated, it is believed that triweekly injections of mapharsen at approximately 1 mg. per kilogram, combined with weekly injections of 0.2 Gm. of bismuth subsalicylate and continued for nine to twelve weeks, will probably "cure" 85 to 90 per cent of cases of early syphilis.

6. (a) The initial reagin titer affected the rate at which seronegativity was obtained but did not affect the ultimate percentage "cured." (b) Within fairly wide limits (fifty-four to eighty-one days) the total duration of treatment also had no effect on the end results. Within that time period occasional lapses in treatment or smaller individual dosages could be ignored, provided the patient eventually received the scheduled total amount of drug. (c) With equal amounts of treatment, secondary syphilis gave significantly more treatment failures than did seropositive primary syphilis.

7. The efficacy of this schedule in the prevention of congenital syphilis, and its efficacy in latent syphilis, are under continued study.

EUGENIA MAECHLING, Ph.D.

NEW YORK

We are presenting a report of 332 cases of early syphilis treated in the past three years with massive doses of arsphenamine by the syringe method, the treatment period being five to six days. Arsphenamine¹ was chosen because of our experience in the rapid healing of syphilitic lesions and the spectacular cures we had witnessed with this drug in early syphilis when other arsenicals had failed, and again because of the excellent results we had obtained in the treatment of early syphilis at the Vanderbilt Clinic over a period of some twelve years with this arsenical. Such observations encouraged us to think that some one should evaluate this drug in an intensive treatment program of early syphilis, i. e. the five day treatment.

We were prompted to undertake this study by the encouraging results of Leifer, Chargin and Hyman,² who treated 382 patients by the intravenous drip method with neoarsphenamine and mapharsen. They reported a completely satisfactory course in 81 per cent of their cases. Further study was carried on by various investigators under this plan or modification of Chargin's

technic. Rattner³ used mapharsen by the intravenous drip method in his series. Schoch and Alexander⁴ used mapharsen by the syringe method daily over periods of two to four weeks. Of 103 patients they followed for six to eighteen months, 77 per cent are in a satisfactory condition. Shaffer⁵ used mapharsen in his series of 430 patients. Cole,⁶ including the results of his own work, has summarized the studies of these and other investigators, including a discussion of some work done by Dr. Rattner subsequent to that mentioned and not reported elsewhere.

SELECTION AND CARE OF PATIENTS

All patients treated were men between the ages of 15 and 64 years, chiefly young, healthy men. One patient had active pulmonary tuberculosis, several had hypertension, 1 had a history of jaundice and a number had various skin eruptions other than syphilitic. Several were obese, and a few were thin and emaciated. All these seemingly defective patients were considered poor risks, but they tolerated the treatment as well, apparently, as the otherwise healthy individuals. Two thirds were Negroes. Most of the cases were supplied by the board of health.

All patients were hospitalized for treatment. The ward was under constant nursing care day and night, and a team of physicians gave the treatments, made all tests and closely observed each patient while in the hospital. The injections were given at three to four hour intervals during the daytime.

Every patient had a complete history and physical examination on admission. Two hundred and ninety-six had positive dark fields, and these dark field examinations were repeated daily until they were negative. Sixty-one cases were seronegative. Titrated blood Wassermann reactions were done on patients entering the ward and before discharge. Only 19 were found to have positive spinal fluid Wassermann reactions. These spinal fluid examinations were repeated at the completion of treatment. The blood and platelet counts were within normal limits. These counts were repeated after completion of the course of treatment. Albuminuria was present in 7 cases on admission. Urinalyses were done daily on all patients during the time of treatment. Eighty-nine cephalin flocculation reactions were slightly to strongly positive on admission and became negative in one week to several months following discharge from the hospital. Dr. Franklin Hanger,⁷ who has made a study of postarsphenamine liver damage and in whose laboratory the latter tests were done, stated (in a personal communication) that these positive reactions before treatment possibly signified liver damage from syphilis. The serum bilirubin and the blood urea nitrogen were found to be within normal limits on admission. These and the cephalin flocculation reactions were repeated when indicated. Frei and Ducrey tests and urethral cultures were done on all patients. Fifty-nine patients were found to have a slightly to a strongly positive Frei test when read at forty-eight hours. Sixty-nine had a

The beds in the ward were lent by the Department of Medicine. Dr. Franklin M. Hanger, associate professor of medicine, did all of the functional liver tests.

From the Department of Dermatology, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

Dr. Walter W. Palmer, professor of medicine, and Dr. J. Gardner Hopkins, professor of dermatology, served in an advisory capacity.

lightly to a strongly positive Ducrey skin test at forty-eight hours, and 21 had positive urethral cultures for gonorrheal organisms. No evidence of syphilitic involvement was found on x-ray examination of the heart or aorta. Electrocardiograms were done on the first half of the series. No noteworthy abnormalities were discovered. Rectal temperature, pulse rate and respiration were recorded on each patient every four hours.

A record was kept of the time required for spirochetes to disappear from surface lesions, of the healing of lesions, of the disappearance of glands and of all reactions to treatment.

After discharge from the hospital the patients were followed weekly in the clinic, where physical examinations and titrated blood Wassermann reactions were done. After the initial period of six weeks the patients were followed monthly.

TREATMENT PLAN

Our procedure consisted in giving arsphenamine in 2 per cent solution by the syringe method three to four times daily for five to six days, depending on the particular variation of our plan. The total dosage ranged from 1.5 Gm. in the beginning of the experiment to

seventh patient, so it was decided that the amount of arsenic could be increased. In order to do this the treatment was extended to six days instead of five, with a corresponding increase in the amount of arsphenamine in each weight group.

Plan Variation 2.—This increase gave the light weights a total of 1.8 Gm., the middle weights 2.55 Gm. and the heavy weights 3.45 Gm.

Forty cases were treated in this group. Sixty per cent had negative dark fields after one day's treatment, 83 per cent were negative after the second day and 95 per cent were negative after the third day. One patient was dark field positive for as long as five days. The reactions remained mild, except for the second case of encephalitis, the fifth patient treated under this new scheme. It soon became evident that some radical change must be made in the treatment program in order to hasten the disappearance of spirochetes from the lesions and to prevent mucocutaneous relapses.

Plan Variation 3.—The first radical departure from the original treatment program was to give the largest doses on the first day and gradually diminish the amount toward the end of the treatment. We gave the injections four times a day and increased the amount

TABLE 1.—Plan Variations in the Treatment with Arsphenamine

Plan Variation	Number of Cases Treated	Number of Days Treated	Number of Injections per Day	Total Amount Arsphenamine Given 1st Day (Gm.)	Total Amount Arsphenamine Given Last Day (Gm.)	Total Amount Arsphenamine Given in the Course		
						Light Weight 100 Lb. to 135 Lb. (Gm.)	Medium Weight 135 Lb. to 165 Lb. (Gm.)	Heavy Weight 165 Lb. to 220 Lb. (Gm.)
1	47	5	3	0.2 to 0.45	0.3 to 0.6	1.5	2.1	2.85
2	30	6	3	0.3 to 0.45	0.3 to 0.6	1.8	2.55	3.45
3	60	6	4	0.45 to 1.0	0.2 to 0.3	2.0	2.60	3.45
4	103	6	4	0.6 to 1.0	0.4	3.0	3.0	3.6
5	27	4*	4*	1.0	1.0	...	3.0	...
6	15	6	4	1.0	0.4	3.4	4.0	4.4
7	37	6	4	1.0	0.4	3.2	3.6	4.0

* Plan 5 consisted in giving 1.0 Gm. of arsphenamine in four divided doses a day on three alternate days.

4.4 Gm. in the latter part of the treatment program. As arsphenamine had never been used in the five day treatment program, we began cautiously with small doses. Experience showed that the reactions were chiefly of a mild sort, so we increased the number of injections from three to four times a day, and the number of days from five to six.

VARIATIONS OF TREATMENT PLAN

We employed seven different treatment plans (table 1), each new plan having been worked out after a study of the results of the preceding one. The dosage was gaged according to the weight of the patient, each group being divided into light weight (100 to 135 pounds, or 45 to 61 Kg.), medium weight (135 to 165 pounds, or 61 to 75 Kg.) and heavy weight (165 to 220 pounds, or 75 to 98 Kg.), so that the light weight received a total of 1.5 Gm., the middle weight 2.1 Gm. and the heavy weight 2.85 Gm. of arsphenamine, given three times a day for five days. The dose was increased each day.

Forty-even patients were treated under this plan. At the end of the first day's treatment, 52.5 per cent of the patients had negative dark fields. Two required four days before their dark fields became negative. Mucocutaneous relapses with positive dark fields began to appear. It quickly became evident that this plan had proved a failure. The reactions had been of an exceedingly mild type except for an encephalitis in the forty-

of arsphenamine to 2.0 Gm. for the light weights, 2.6 Gm. for the middle weights and 3.45 Gm. for the heavy weights. We were prompted to begin the treatment with large doses on the first day because of the lack of serious reactions and of the patient's good general condition at this period of treatment. Furthermore, we were convinced that the greater the initial dosage in the first day or two of treatment the more favorable would be the result. Large doses in the beginning had the added advantage that, should the treatment have to be discontinued because of reactions, the patient would already have received a substantial part of his treatment in the first two days, virtually half the total amount of arsphenamine planned for the course.

Of the 60 patients treated under this third plan, 96 per cent were negative on dark field examination after the first day of treatment and 100 per cent were negative at the end of the second day, a decided improvement over the other two plans. The serologic responses were most encouraging, a number of patients becoming negative and others showing pronounced reduction in the intensity of the reactions. While frequency and intensity of all the reactions were somewhat increased, especially the initial rise in temperature, they were not serious. Even though the individual had a Herxheimer reaction with a temperature of 104.2 F., the injection of arsphenamine was given. The next morning the patient's temperature would be normal and he would be none the worse.

After six months infectious relapses began to make their appearance. A study was then made of all cases treated to date in each variation of our plan of treatment, and it was observed that no patient who had received as much as 3.0 Gm. of arsphenamine had suffered a relapse. It appeared that if each patient could be given a minimum of 3.0 Gm. that might be the answer to our problem.

Plan Variation 4.—This was devised whereby the light weight and middle weight groups each received 3.0 Gm., and the heavy weight group 3.6 Gm. One hundred and three patients were treated in this plan. All except 1 had a negative dark field after the first day of treatment. While the incidence of initial febrile reactions remained about the same as in the previous group treated under plan 3, there was a 6 per cent increase in toxic erythema. Optimism over this plan of treatment was soon dispelled by the appearance of mucocutaneous relapses in spite of the minimum 3.0 Gm. dose that had been given.

TABLE 2.—Time Required for Dark Fields to Become Negative

Plan Variation	Dark Field Positive Cases	Negative After 1st Day, per Cent	Negative After 2d Day, per Cent	Negative After 3d Day, per Cent	Negative After 4th Day, per Cent	Negative After 5th Day, per Cent
1	40	52.5	90.0	95.0	100.0	
2	38	60.5	83.7	95.3	97.9	100.0
3	30	94.0	100.0			
4	26	98.9	100.0			
5	27	100.0				
6	18	100.0				
7	37	100.0				

TABLE 3.—Outcome of Treatment

Number of cases	332
Observed 6 months to 3 years	178
Observed 9 to 11 months, outcome pending (2%)	3
Clinically and serologically negative (66%)	118
Unsatisfactory outcome (32%)	57
Cutaneous relapses with positive dark field (Negative blood Wassermann before cutaneous relapse—24)	56
Serorelapse after becoming seronegative	9
Did not become serologically negative in 12 months	12
Failed to become serologically negative sometime during observation regardless of outcome	27

Plan Variation 5.—Examination of the blood arsenic reports done in the cases showed a sharp rise in the arsenic level on the second day and a tendency toward a more gradual rise on the last days of the treatment. By giving 1.0 Gm. in four divided doses every other day for a total of 3.0 Gm. in five days, we thought that the intervening day of rest would allow for the excretion of sufficient amounts of arsenic to maintain the blood arsenic at a more even level. All 27 patients treated under this plan were middle weights. All dark fields were negative at the end of the first day's treatment and there was a very satisfactory serologic response, but even though we have followed only 13 patients for six months we have had 3 mucocutaneous relapses. There was an increase both in initial rise in temperature of 16 per cent of the patients and in secondary rise in temperature of 10 per cent.

Plan Variation 6.—Although it was apparent from the increased number of reactions that we were approaching the highest total amount of arsenic that an individual could tolerate in six days, we decided to make an increase in the amount of arsphenamine to 1.0 Gm. the first day for each patient and gradually

reduce the dose toward the end of treatment. In this plan the light weights received a total of 3.4 Gm., the middle weights 4.0 Gm. and the heavy weights 4.4 Gm. in six days. Eighteen patients were treated according to this outline. All dark fields were negative by the completion of one day's treatment. Of the 8 patients that we have followed for at least six months, no relapses have occurred. This group has given the best clinical and serologic results of any so far treated, but at a cost of great increase in reactions. Toxic erythemas occurred in 55.5 per cent of the patients, secondary fevers in 89 per cent and toxic neuritis in 39 per cent. Although not severe, these reactions have been so frequent as to cause us to make a reduction in the dosage.

Plan Variation 7.—The last plan variation, 7, called for 1.0 Gm. of arsphenamine the first day in all groups of patients. For the light weight group we gave a total of 3.2 Gm., the middle weight group 3.6 Gm. and the heavy weight group 4.0 Gm. Thirty-seven patients were treated in this group. All dark fields were negative by the end of the first twenty-four hours of treatment. Although only 2 patients in this group were followed for six months, 1 had a mucocutaneous relapse on the eighty-first day after completion of the treatment.

OUTCOME OF TREATMENT

The time required for the disappearance of spirochetes from the lesions varied according to the plan of treatment and the amount of arsphenamine used. In the first group of patients treated in plan 1, there were only 52.5 per cent negative dark fields after the first day of treatment. With each successive increase in the amount of arsphenamine given the first day there was a greater number of dark field negative cases after twenty-four hours. It was not until we reached the fifth plan, in which each patient received 1.0 Gm. of arsphenamine the first day, that 100 per cent of the dark fields became negative within twenty-four hours from the beginning of treatment, as shown by table 2.

Healing of all surface lesions was prompt and usually complete by the time the patient was discharged from the ward in seven days, irrespective of the plan used. Within twenty-four hours after beginning treatment the open lesions were noticeably drier, swelling was less and epithelization of the chancre was usually complete by the time of discharge. All secondary lesions healed promptly, the macular lesions disappearing within the first one or two days. All lichenoid and papular lesions became flat and healed completely, or practically so, within a week. The enlarged glands were the last to disappear, sometimes requiring two or three months or longer to subside.

Of the 332 cases treated by all plans, we shall discuss only the 178 that have been followed from six months to three years. One hundred and eighteen (66 per cent) are clinically and serologically negative and have normal spinal fluids. Three cases are still serologically positive at nine, ten and eleven months respectively. Their final outcome is pending (table 3).

Fifty-seven patients had an unsatisfactory outcome. Of this number 36 had cutaneous recurrences with recovery of spirochetes on dark field examination. Two of these cases that were dark field positive showed negative blood Wassermann reactions at the time of the recurrence. Also of these 36 cutaneous relapses 24 had become serologically negative for varying periods of time before their recurrence.

Of the 57 patients with unsatisfactory outcome 12 failed to become serologically negative by the end of a year, and 9 patients became negative but reverted to positive.

It will be seen then that of the entire 178 cases only 27 failed to become serologically negative at some time during the observation.

All cases that have not become serologically negative after one year's observation are classed as treatment failures.

Each patient had a spinal fluid examination before the treatment was begun. Of the entire group only 19 were found to have positive spinal Wassermanns in varying degrees. Four of these have become negative, 8 have been lost from observation, 4 had positive spinals at the end of one year and were successfully treated, and the remaining 3 are under observation.

Of the 57 unsuccessfully treated patients, 18 were retreated in the ward with a more intensified plan than was used originally. On the whole they tolerated the treatment better the second time, with the increased amount of drug, than they did originally. Further, it is interesting to note that all these patients except 1 had a Herxheimer reaction on the first or second day of the second course of treatment, with a rise in temperature to 100 F. or over, just as they had had in the first course. Eight of these patients had temperatures that rose to 102 F. or over. One patient had a nitritoid reaction with the first injection of the second course.

None of the relapsed cases that were retreated successfully in the ward have been added to the list of cures. The remaining relapsed cases were treated as ambulatory patients in the clinic. Two cases have had a second relapse.

Of all patients treated 69 are in the armed forces and 38 are in the Merchant Marine. Thirty-nine other patients are from out of the city and are classed as transients. One is in a sanatorium. Five are in defense jobs and are unable to report to the clinic. Three are dead: 1 in the ward, previously referred to, 1 killed in an automobile accident and the third dead from an unknown cause. We have lost 70 patients (20 per cent) from our clinic, and neither the social service department nor the board of health has been able to find them.

Twenty-one white and 4 Negroes, totaling 25 patients, ranging in age from 40 to 64, had an almost perfect follow-up. Forty-eight patients of the entire group treated were under 20 years of age, 42 Negro and 6 white. The latter group has been very difficult to follow.

LABORATORY ARSENIC STUDIES

A daily blood arsenic determination was made on each patient.⁸ The specimen was taken each morning before the first treatment. This represented a time interval of fourteen to fifteen hours between injections.

The blood arsenic levels revealed interesting facts which we believe are worthy of special mention. Most of the patients had a blood arsenic content that was normal or only slightly increased on admission, and every patient following the first day of treatment had an increase in arsenic that reached a maximum on the third to the sixth day, depending on the amount of arsenic given in each plan. There was no uniformity in the amount of arsenic retained or in the date on which retention reached its height, even when all

patients received the same amount of arsphenamine. There was, however, a definite tendency for a greater retention of arsenic as the age incidence of the individual increased. Moreover, there was in most cases a decrease in the amount of arsenic in the urine of the older patients.

There was also a decided increase in the incidence of reactions in patients 34 to 56 years old, whereas the minimum number of patients showing reactions was under 34.

The young men of both the light weight and the middle weight groups disposed of their arsenic better than did the heavy weight group, as revealed by the arsenic blood level curve. Even though the total amount of arsphenamine was less per kilogram of body weight in the heavy weight group there was greater retention than in the light weight patients who received larger amounts of arsphenamine per kilogram of body weight. This bears out our clinical experience, namely, that dosage cannot be satisfactorily gaged according to body weight. For this reason experimental work for standardization of dosage and the like on selected laboratory animals of relatively uniform physique cannot be carried across to human beings who are so different in build, age, health and so on.

The quantity of arsenic retained was virtually the same on the sixth day of treatment in the patients

TABLE 4.—Severe Reactions

treated with small ascending doses of arsphenamine as it was in the patients to whom large doses were given on the first day and diminished toward the sixth day. This was true when the same amount of arsenic was given in each procedure.

Three things stood out quite definitely in the study: (1) There was always a retention of arsenic long after cessation of treatment; (2) all reactors showed a greater retention of arsenic for a longer period of time than nonreactors; (3) the more arsenic received, the greater was the retention.

Patients receiving 1.0 Gm. of arsphenamine every other day for a total of 3.0 Gm. in five days had a definite spiking increasing blood arsenic curve, of the same type in each case.

The complete report of our findings of arsenic in the 332 cases studied will be included in detail in another paper.

REACTIONS TO TREATMENT

There were 12 severe reactions, 1 ending fatally. These included 2 of encephalitis with recovery, 3 of hepatitis (1 ending in death), 1 in an alcoholic addict, 2 of exfoliative dermatitis (1 mild), 3 of persistent neuritis and 2 of blood dyscrasias (table 4).

The first case of encephalitis appeared early in the experiment in a 20 year old Negro under the first plan of treatment in which the patient was given his injections three times a day for five days, receiving a total of 2.1 Gm. of arsphenamine. He developed a secondary rise in temperature during treatment, and on the second day his temperature reached 102.4 F. His

8. Macchling, E. H., and Flinn, F. B.: Colorimetric Determination of Small Amounts of Arsenic in Biologic Material, *J. Lab. & Clin. Med.* 15: 779, 1930. Macchling, E. H.: Separation and Determination of Bismuth and Arsenic in Biologic Material, *ibid.* 15: 1058, 1933.

temperature remained elevated and two days after cessation of treatment he had a slight tremor of the fingers, which was most noticeable when he was feeding himself. On the third day aphasia was apparent and he was unable to speak distinctly. He was stuporous, had a blank expression, would not obey commands and could not swallow, so that he had to be fed by stomach tube. He had to be catheterized daily, and his bowels were involuntary. He was given fluid and dextrose by vein. A spinal puncture was not done. On the fourteenth day he began to improve and was discharged thirty-three days after his admission, apparently none the worse for his experience except for urinary urgency. His spinal fluid was negative before treatment and has remained so. His blood Wassermann reaction reverted to negative in two months and has remained so.

The second case of encephalitis appeared eight days after completion of treatment in a 26-year-old Puerto Rican. He had received a total of 2.4 Gm. of arsphenamine, given three times a day for six days. He was nauseated and vomited on the last two days of treatment and had a mild nosebleed. His treatment had to be interrupted on the sixth day because of a secondary rise in temperature. Instead of receiving 2.55 Gm. of arsphenamine, as outlined, he received only 2.4 Gm. The temperature reached 104 F. after the treatment was stopped and was followed by a toxic erythema of a pronounced type that had a dark red to an almost cyanotic color with purpura developing distal to where a tourniquet was applied on his arm.

On the fifteenth day of his hospitalization, one day after his temperature had fallen to near normal, he developed a tremor in his hands, more pronounced on feeding himself. Within a period of twelve hours he became aphasic, could not obey commands and could not speak clearly. A lumbar puncture was attempted by another department, during which he had a convulsion. Four cc. of grossly bloody fluid was obtained which was thought to be due to trauma. His treatment consisted of dextrose infusions twice daily and sedation as required. He was semicomatose for four days, when he began to improve. His recovery was complete and he was discharged thirty-three days after his admission, apparently well. His blood Wassermann reaction was negative six months after treatment.

We had no way of foretelling that either patient would have encephalitis until the first signs of tremor appeared, followed later by aphasia.

Of the 3 cases of hepatitis, the first occurred sixty-three days after discharge from the hospital:

He was a chronic alcoholic addict aged 21. His hepatitis followed one of his periodic alcoholic bouts. This patient was in treatment plan 3. He received 2.0 Gm. of arsphenamine and tolerated his treatment well. His liver function tests had been normal on his first admission to the hospital and on subsequent clinic visits. He recovered from his hepatitis after a stay of fifteen days in the hospital. His blood Wassermann reaction became negative and remained so for about one and one-half years before he was taken into the Army.

The second patient, aged 22, developed symptoms of hepatitis three days after receiving 3.2 Gm. of arsphenamine in five days. There was no history of previous icterus or disease of the liver. His temperature rose on the fifth day, and treatment was stopped immediately. His cephalin flocculation tests rose from negative to 4 plus, together with a rise in temperature to 104.4 F., and a toxic erythema. Clinical jaundice was evident three days after treatment had been stopped.

The patient was nauseated throughout his treatment period and vomited. He ate very little food during this time and was given 1,000 cc. of 5 per cent dextrose solution intravenously twice daily, starting with the second day of treatment. His liver became enlarged and tender. The patient complained of pains all over his body and generalized weakness. He had pain also across his chest. The night of the sixth day he had a severe epistaxis, estimated at about 400 cc. His blood pressure rose from 140 systolic to 186 systolic. On the seventh day of his hospitalization he suddenly developed short, fast respirations and tachycardia. The heart and lungs were normal on physical examination except for a high right diaphragm. His temperature fell to 99.4 F. He had to be placed in an

oxygen tent. He grew gradually weaker and died on the evening of the ninth day after admission. Permission for postmortem examination could not be obtained.

The third patient, aged 31, showed no clinical evidence of jaundice but the diagnosis was made on the basis of a rise in cephalin flocculation from negative to 3 plus. Also his cholesterol blood level fell to 78 mg. per hundred cubic centimeters. He had a secondary rise in temperature to 102.4 F. and a toxic erythema. His total treatment was 3.2 Gm. of arsphenamine in six days. He had an uneventful recovery after a stay of twenty-one days in the hospital.

A transient leukopenia was observed in 2 patients:

The first was a 25-year-old Negro who had received 1.7 Gm. of arsphenamine in six days. His initial leukocyte blood count fell from 5,000 to 2,480 per cubic millimeter and polymorphonuclear leukocytes fell from 74 per cent to 43 per cent. The patient was given three small blood transfusions over a period of ten days. He recovered completely. His only symptom was a daily temperature that fluctuated between 102 and 104 F. The temperature fell to 98.6 F. after the blood transfusions and the blood count became normal. He has remained clinically and serologically negative for over two years.

The second patient with leukopenia, a 28-year-old Negro who received 2.4 Gm. of arsphenamine in six days, showed symptoms of agranulocytosis on the seventeenth day after treatment had been stopped. His leukocyte count of 8,560 per cubic millimeter of blood on admission with 70 per cent polymorphonuclear leukocytes fell to 6,400 leukocytes, with an absence of granular forms. Frequent blood counts in this interval revealed a gradual reduction of leukocytes and granulocytes. His recovery was spontaneous, without treatment of any kind, and complete in two and a half weeks. He too has been serologically and clinically negative for more than a year.

Three patients with severe neuritis have been persistent for approximately nine months, one year and one and one-half years respectively. Their ages were 26, 31 and 34 years, and they received 3.4 Gm., 2.0 Gm. and 3.0 Gm. respectively. Each patient complained of "pins and needles" sensation in the feet. They also had dull pain in the calves and knees. There was no ataxia. Two patients have continued to work. The third patient has an active pulmonary tuberculosis and is now confined to a sanatorium with that disease. All 3 are still serologically and clinically negative.

Of 2 patients with exfoliative dermatitis, the first patient, aged 33, developed dermatitis ten days after he was discharged from the hospital. He received 3.6 Gm. of arsphenamine. Treatment was discontinued on the fifth day because of a rise in temperature followed by a toxic erythema. He was discharged on the fourteenth day, well except for a little itching of the forearms and flanks. After being out of the hospital ten days he developed a generalized exudative dermatitis accompanied by edema. He was readmitted and hospitalized for three weeks. He had general thinning of hair and exfoliating of all nails. This patient has remained clinically and serologically cured for approximately eight months of observation.

The second case of dermatitis developed fourteen days after discharge from the hospital. A man aged 33 was in the seventh treatment plan and tolerated his drug well except for a pain in the pit of his stomach on the last day. His total dose was 3.9 Gm. of arsphenamine. This patient had a dry, itching, lichenified eruption that was generalized, with a few areas of exudation. He remained ambulatory and the condition cleared in approximately three weeks without any other symptoms.

There were numerous minor reactions, such as an initial rise in temperature the first day that appeared in a great majority of cases and returned to normal the

next day. Although the temperature may have risen to 104 F. in the first afternoon, the regular injection of arsphenamine was given and the temperature would be normal the next day. Patients with secondary syphilitic manifestations often had redness and swelling of the surface lesions and tenderness of the glands. These too disappeared the following morning.

Secondary rises in temperature and toxic erythemas occurred near the end of the course, and mild neuritis usually appeared about two weeks after cessation of treatment. The neuritis was evidenced by transitory numbness and tingling of the hands and feet that usually cleared in a few days to several weeks.

The aforementioned reactions were the ones most commonly encountered, the incidence of their frequency increasing as the amount of the drug was increased. The occurrence of rise in secondary temperature over 100 F. was 25 per cent in the first group treated and increased to 89 per cent in patients receiving the greatest amount of arsphenamine. Mild neuritis rose from 2 per cent to 35 per cent. Toxic erythemas increased from 8 per cent to 40 per cent. All toxic erythemas were preceded by a rise in temperature of 100 F. or over.

These reactions, as a rule, were of no serious import and often were so mild as not to have been noticed by the patient or were brought out only on close questioning.

Traces of albumin were noted in the urine in 18 per cent of the cases. Ten cases showed as much as 3 plus albumin in the urine (based on 1 plus to 4 plus reaction). All these subsequently cleared following completion of treatment. Albumin, which was found in the urine of 7 patients before treatment was begun, disappeared completely in 5 of the cases during the course of the treatment.

Jaundice, without evidence of hepatitis, as demonstrated by negative cephalin flocculation reactions, was observed in 3 patients following toxic erythemas. Their recoveries were complete.

Vomiting at some time during the course of the treatment occurred in 22 per cent of the cases. Diarrhea, when present, usually occurred on the first day and was present in 10 per cent of the cases.

Still milder reactions included anorexia, nausea, abdominal pain, transient pruritus, herpes simplex, epistaxis, watering of the eyes, buzzing of the ears, herpes zoster and herpes progenitalis. All were transient.

OBSERVATIONS

A study of approximately 2,500 titrated Wassermann reactions showed that the higher the titer the longer the time required for the Wassermann reaction to become negative; the weaker the titer, the shorter the time. Patients with the highest titer, i. e. positive reaction in a dilution of 1:160 of the whole serum, required an average of twenty-two weeks to become negative and to continue so. Cases with titers positive in a 1:80 dilution required an average of fifteen weeks to become negative; those with 1:40 dilution, fourteen weeks; 1:20 dilution, eleven weeks, while those with a 1:10 dilution required 9.7 weeks to become negative. Cases showing a 4 plus reaction with a negative titer required an average of 8.9 weeks, while those with a 1 plus to 3 plus Wassermann reaction required only 4.1 weeks to reverse. The patients with seronegative primaries in which the blood Wassermann reaction

became positive during the treatment required 4.4 weeks to become completely negative again.

Those patients having positive titers greater than the usual 4 plus in undiluted serum were not only more resistant to treatment but had more than twice the number of recurrences than were found in the cases in which the initial blood Wassermann reaction was 4 plus or less: 37.2 per cent in the former as compared to 14.2 per cent in the latter.

These findings indicate that the earlier the treatment is begun in the syphilitic, preferably before the Wassermann reaction becomes positive (seronegative primary), the greater the chances of cure. One would infer that a patient whose blood Wassermann reaction does not become negative within six months from the beginning of intensive arsenotherapy and remain so should in all probability be considered inadequately treated.

The foregoing observations suggest that a syphilitic patient who becomes serologically negative after the expiration of six months from the date of his last treatment does so by the retention of arsenic or by his own body resistance.

TABLE 5.—Moderate Reactions

Plan variation.....	1	2	3	4	5	6	7
Cases treated.....	47	40	60	103	27	18	37
Primary rise in temp....	72.5%	82.5%	90.0%	80.5%	96.3%	94.4%	94.5%

Toxic erythema Mifflin....	8.5	12.5	10.6	22.3	14.8	55.5	35.7
Transient neuritis.....	2.1	7.5	11.4	12.6	14.5	33.3	28.5

TABLE 6.—Weeks for Blood Wassermann Reaction to Become Negative

Positive on Admission	Weeks to Become Negative
1/160 dilution titer.....	22
1/80 dilution titer.....	15
1/40 dilution titer.....	14
1/20 dilution titer.....	11
1/10 dilution titer.....	9.7
Four plus in undiluted serum.....	8.9
One plus to 3 plus in	4.1
Negative that became	4.4

Fifty-nine patients who were over 33 years of age became and have remained serologically and clinically cured to date with the exception of 3, and the latter patients had only serologic relapses. The fact that this same age group showed the greatest retention of arsenic would tend to substantiate our belief that the patients who became spontaneously cured long after cessation of treatment did so by the arsenic stored in their systems.

The percentage of cures was the same in patients who received a total of 3.0 Gm. of arsphenamine given in 1.0 Gm. doses on alternate days as in the patients receiving the same total amount of arsphenamine given daily.

The patients who received the largest dosage of arsphenamine (70 mg. per kilogram of body weight) had no reactions either while under treatment or subsequently and to date have remained serologically and clinically negative.

All patients receiving 1.0 Gm. of arsphenamine the first day were dark field negative within twenty-four hours after their first injection.

Sixty-one patients had seronegative primary lesions, 47 of whom reverted to positive while under treatment.

A large dose of arsphenamine on the first day of treatment in early syphilis was more effective than a small dose in rendering the lesions dark field negative, and the serious toxic reactions were no greater.

The greater the amount of arsphenamine given, the more frequent was the occurrence of primary fever and secondary fever, and the more severe the toxic erythema, nausea, vomiting, neuritis and dermatitis.

Patients reacting with fever or toxic erythemas showed no higher percentage of cures than those without such reactions.

All 12 patients who had severe reactions, hepatitis, encephalitis, dermatitis, blood dyscrasias and neuritis became serologically negative and have remained so.

Twenty-eight per cent of patients who had neuritis had symptoms within one week after finishing the treatment.

Both cases of encephalitis occurred with relatively small doses of arsphenamine, 2.1 and 2.4 Gm. respectively, given in fractional doses three times a day in the five and six day plans. Neither patient had spinal drainage, and both recovered.

Patients in the light weight groups who received the smallest amount of arsphenamine had the fewest number of cures.

Of the 36 mucocutaneous recurrences, 10 showed chancres with enlargement of the regional glands and recovery of spirochetes from the chancre. Some initial lesions were located at different sites from the original chancre. There was no way to distinguish the lesions in the recurring mucocutaneous relapses from those observed in the original infection.

No case of thrombocytopenic purpura was found clinically, nor was there a depression in the platelet counts that were done repeatedly on all patients.

Patients receiving over 55 mg. of arsphenamine per kilogram of body weight had the most satisfactory outcome.

Of the entire series treated, only 27 patients failed to become serologically negative.

SUMMARY

Three hundred and thirty-two patients with early syphilis were treated three or four times daily over five or six day periods with arsphenamine by the syringe method.

Of 178 patients followed for six months to approximately three years, 118 have remained clinically cured with negative blood Wassermann and spinal fluids.

Fifty-seven patients had unsatisfactory outcomes. Thirty-six of these had mucocutaneous relapses with recovery of spirochetes.

There was one death from toxic hepatitis. Two patients had encephalitis, 3 hepatitis, including the one mentioned, 3 severe neuritis, 2 exfoliating dermatitis and 2 blood dyscrasias.

CONCLUSIONS

As a result of our experience in this study we are forced to the opinion that treatment of early syphilis with arsphenamine by the multiple syringe method over a period of five or six days is ineffective, dangerous, expensive and altogether unpractical.

We are convinced that any such five or six day intensive treatment plan with arsphenamine, using the multiple syringe method, must be followed by additional therapy of a heavy metal, fever or both to be successful.

COMBINED FEVER AND ARSENO-THERAPY

IN THE INTENSIVE TREATMENT OF EARLY SYPHILIS

EVAN W. THOMAS, M.D.

AND

GERTRUDE WEXLER, M.D.

NEW YORK

Since Ehrlich's discovery of arsphenamine, the treatment of syphilis by the intensive use of arsenical drugs has been associated with the hazard of toxic reactions. The introduction of arsenoxide, which permitted smaller doses of arsenic with equally good therapeutic results, lowered the incidence of toxic effects but failed to eliminate them.

Eagle and Hogan¹ in their reports on the toxicity of arsenoxide, calculated from experiments in animals, showed that the margin of safety in man was only about 3.0 when a total dose of 1,200 mg. of mapharsen was given to the average adult in five to ten days. They considered this margin of safety dangerously low. When mapharsen alone is used in the rapid treatment of syphilis, clinical experience indicates that a total of 20 to 30 mg. per kilogram of body weight is needed for the best results. From our experience at Bellevue Hospital, Eagle and Hogan were correct in considering a schedule of therapy requiring this amount of mapharsen in a five to ten day period too dangerous for routine use.

A false sense of security can easily be acquired in intensive arsenotherapy, because one may give a hundred treatment courses with relatively large amounts of mapharsen and encounter no serious difficulty only to be rudely awakened by a grave reaction in the very next treatment. So far no one has collected into a single statistical table all of the available data on the toxic effects of intensive arsenotherapy. When this is done for treatment schedules where mapharsen alone was given in five to ten days, it will probably be found that the incidence of encephalopathy has been over 1 per cent. This at least was our experience at Bellevue Hospital.

Following our first death from arsenical encephalopathy, we tried lowering the total dose of mapharsen and turned to fever to reinforce the action of these lowered doses. Originally we believed that the combination of fever with chemotherapy not only would permit smaller amounts of mapharsen but might also protect against its toxicity, as Rose, Simpson and Kendell² suggested. Consequently we completed several relatively large series of treatment courses using various combinations of mapharsen with fever induced by typhoid vaccine. Every one of these schedules called for two injections of about 60 mg. of mapharsen

on at least one day of treatment. The incidence of arsenical encephalopathy, however, continued to be over 1 per cent, although most of the reactions were less severe because of the lower total dose of mapharsen. Thus it was evident that fever failed to protect against the toxicity of arsenic. And, in fact, Carpenter and his co-workers² recently have reported that in animals fever actually increases the toxicity of mapharsen; but it also enhances the effectiveness of arsenotherapy and so permits smaller amounts of drug.

Table 1 shows that among 321 treatment courses given at Bellevue Hospital with mapharsen alone in a six to ten day period the incidence of encephalopathy was 1.6 per cent. In a series of 588 treatment courses with combined fever and mapharsen in which two injections of about 60 mg. of mapharsen were given on at least one day of treatment, the incidence of encephalopathy was 1.36 per cent. In the total series of 909 treatment courses encephalopathy occurred in 1.43 per cent and the mortality rate was 1 in 300.

The advantages of rapid treatment for early syphilis to both the community and the patient are so great that one might justify even a mortality of 0.3 per cent if safer means of rapid cure were unavailable. But obviously our task was to find safer schedules of treatment. As we have as yet no means of determining in advance the tolerance of individuals for arsenical drugs, we attempted to find the dose of mapharsen which could be given in five to ten days without danger to those particularly susceptible to arsenic. To determine this as well as the effectiveness of the therapy, it was necessary to give relatively large series of treatment courses. A death attributed to treatment made us change the schedule of therapy, but it was not until after our third fatality that we finally found a method of treatment which proved acceptable.

In formulating our schedules of therapy we had to consider not only the total amount of mapharsen which could safely be given in five to ten days but also the maximum single dose which could prudently be given at daily intervals. By July 1942 we determined that the maximum single dose of mapharsen per day was approximately 1 mg. per kilogram of body weight and the minimum period of treatment was ten days. With this schedule the average patient received ten daily injections of about 60 mg. of mapharsen. To reinforce treatment with this low dosage, four fevers induced by typhoid vaccine were included in the ten days.

The fevers as a rule were given on the second, fourth, sixth and eighth days. The vaccine used was obtained from the New York City Department of Health and contained 1,000 million *B. typhosus*, 750 million *B. paratyphosus A* and 750 million *B. paratyphosus B*. per cubic centimeter. The first fever was induced with an initial injection of 0.1 cc. of this vaccine intravenously, the second with 0.2 cc., the third with 0.4 cc. and the last with 0.6 cc. From one and one-half to two hours after the initial injection another dose was given of equal amount in most cases. The response to these injections varied, but in general these doses caused a fever of at least 104 F. for about four hours.

The induction of fever with typhoid vaccine causes discomfort to patients, but this can usually be alleviated with sedatives, such as isonipecaine or, if necessary,

morphine. In our opinion the induction of fever with typhoid vaccine is safer than with electropyrrexia. The latter is more effective therapeutically, because more sustained and higher fevers can be produced, but it is less practical because the necessary equipment and personnel for inducing fevers with electropyrrexia are not usually available. At Bellevue Hospital we have given typhoid vaccine intravenously in over 1,650 treatment courses without a single serious reaction due to the vaccine.

In June 1943, further to enhance the effect of treatment, we added bismuth to our schedule of rapid treatment, giving intramuscular injections of 0.1 Gm. of bismuth salicylate in oil on the first, third, seventh and tenth days of therapy. Thus, our standard chart of therapy came to be as shown in table 2.

By May 1, 1944 we had given 1,163 treatment courses according to this plan without a single fatality. Only 3 very mild cases of encephalopathy were encountered. The diagnosis in all 3 was made chiefly by finding increased cells and protein in the spinal fluid. One patient developed an agranulocytosis, with complete recovery after a single transfusion with whole blood.

TABLE 1.—Cerebral Reactions

	Mapharsen Only	Mapharsen and Typhoid 7-8 Day Treatment	Total

.....	x	x	x	x			x	x		x
.....					0.1	0.2	0.4	0.6		

Unfortunately, this record was broken even as this paper was being written. On May 5, 1944 a white woman with secondary syphilis, who was six months pregnant, developed encephalopathy following her fifth injection of 70 mg. of mapharsen and died. During the five days of treatment she had had only one fever induced by typhoid vaccine. This tragic accident again shows that, when arsenical drugs are used, there is always the danger of a fatal accident in a person who has a definite sensitivity to arsenic. Fatal arsenical encephalopathy has occurred after only two injections of nearsphenamine given five days apart; and as long as syphilis is treated with arsenic the rule of constant alertness by those administering the treatment can never be broken. Arsenical encephalopathy strikes like a bolt from the blue, but in many cases fatal reactions can be prevented by the caution which comes from experience. We have found that the apprehensive, worrying type of individual demands special attention. It is also probable that pregnancy adds to the risk of intensive arsenotherapy. Our recent fatality occurred in a woman who was both apprehensive and pregnant. In addition, her treatment was started at a time of confusion, when the syphilis service at Bellevue Hospital was being moved to new quarters.
